attributable to contamination by leucocytes. Contamination by leucocytes accounted for approximately 3-4 per cent of the mean activity of pyruvate kinase in haemolysates of relatively young red cells and for approximately 2 per cent of the mean activity of this enzyme in haemolysates of relatively old red cells. The results indicate that the activity of pyruvate kinase in the normal human red cell decreases markedly as the cell ages *in vivo*. These findings coincide with the results of investigations reported by Tanaka, Valentine and Miwa<sup>9</sup>. The results suggest that a decrease in activity of pyruvate kinase sustained during ageing of the normal human red cell may be important in senescence of the cell.

Table 1. NORMAL HUMAN RED CELLS SEPARATED BY SERIAL CENTRIFUGATION INTO FRACTIONS CONTAINING RELATIVELY YOUNG AND RELATIVELY OLD CELLS

P < 0.001

P < 0.001

\* Activity of glucose-6-phosphate dehydrogenase, assayed by a modification of the method of Glock and McLean (ref. 7) similar to that used by Zinkham and Lenhard (ref. 8), expressed as  $\mu$ moles nicotinamide-adenine dinucleotide phosphate reduced/g haemoglobin/h.

† Activity of pyruvate kinase, assayed by a modification of the method described by Tanaka, Valentine and Miwa (ref. 9) (modifications consisted of doubling the concentration of adenosine diphosphate and trebling the concentration of phosphoenolpyruvate in the assay mixture), expressed as  $\mu$ moles nicotinamide-adenine dinucleotide formed/g haemoglobin/min.

‡ Evaluated by Student's *t*-test as outlined by Fisher (ref. 10).

It has not been established, however, that activity of pyruvate kinase falls below a rate-limiting level during the life span of the normal red cell. Hexokinase has been considered a pacemaker of glycolysis in the human red cell and evidence has been presented indicating that activity of hexokinase decreases substantially as normal red cells age *in vivo*<sup>3</sup>. Many other age-related changes in the human erythrocyte have been reported<sup>12</sup>. Considerable additional information will be required for clear delineation of the factors which limit the survival of the normal human red cell.

This work was supported by the Medical Research and Development Command, Office of the Surgeon General, Department of the Army, under contract DA 49-193-MD-2413 with the University of Chicago and, in part, by the Douglas Smith Foundation of the University of Chicago. The investigations were made possible through the co-operation of inmate volunteers and the administrative staff of the Illinois State Penitentiary, Stateville Branch, Joliet, Illinois.

## PATHOLOGY

## Tumour Transplantation: a Simple Technique

NUMEROUS techniques of tumour transplantation have been used since Hanau<sup>1</sup> established the transplantability of animal tumours in 1889. One of us reported a technique using a curved surgical needle in 1963 (refs. 2 and 3).

We have now developed an even simpler method of tumour transplantation which makes use of a modified shoemaker's sewing machine needle with the tip ground down almost to the eye (Fig. 1). A 1-3 cm tumour is suitable for transplanting purposes. The donor animal is anaesthetized and immobilized on a cork board. The shoemaker's needle is plunged once into the unexposed tumour, removed and inserted horizontally into the unprepared thigh of the unanaesthetized recipient. As the needle is withdrawn a finger is pressed firmly against the thigh. The five or ten thousand tumour cells that were initially caught in the eye of the needle remain in the recipient. One donor tumour can be used for twenty or more recipients.

Fig. 1. *a*, Shoemaker's needle, ground down. *b*, Tip of needle empty ready for plunging into donor tumour. *c*, Tip of needle full after being plunged into donor tumour. *d*, Tip of needle relatively empty after withdrawal from recipient thigh.

A *C<sub>3</sub>H* rhabdomyosarcoma transplanted using this technique becomes evident in two or three weeks in almost 100 per cent of the recipients.

## IMMUNOLOGY

## Failure of Spleen Cells from Immunologically Tolerant Mice to form Antibody Plaques to Sheep Erythrocytes in Agar Gel

DURING the past decade there have been numerous investigations concerned with establishment of specific immunological tolerance or unresponsiveness to either viable tissues or to a variety of non-living antigens, such as soluble serum proteins, bacterial products, and mammalian or avian erythrocytes<sup>1,2</sup>. Most investigators believe that tolerance is due to a central inhibition of antibody formation and not to masking or binding of antibody by excess antigen<sup>3</sup>.

Acquired tolerance to non-living antigens is often demonstrated by lack of an expected immune response, such as failure to demonstrate circulating antibodies following immunization, failure to induce anaphylactic shock or an Arthus reaction, or failure to establish delayed or immediate skin reactivity following attempted sensitization. It has not been unequivocally established in such investigations whether or not the lack of demonstrable immunological activity or suppressed antibody titres is caused by absence of antibody-forming cells, or due to formation of low concentrations of antibody by relatively normal numbers of immunologically competent cells.

Fluorescent antibody investigations by Sercarz and Coons<sup>4,5</sup> and cell transfer work by Brooke and Karnowsky<sup>6</sup> have demonstrated an absence of cells forming specific antibody to a soluble serum protein antigen or to pneumococcal polysaccharide in tolerant adult mice. Others have also reported failure to transfer specific antibody-forming activity with lymphoid cells from tolerant donors<sup>7-9</sup>. This communication is concerned with investigations utilizing the 'antibody plaque' technique of Jerne<sup>10</sup> to demonstrate directly the relative absence of haemolysin-forming cells in young mice receiving throughout early life tolerance-inducing injections of sheep red blood cells.

For these experiments, litters of new-born *NIH* albino mice were injected intraperitoneally with 0.05-0.1 ml. of a 50 per cent suspension of washed sheep red blood cells twice a week from birth to shortly before testing. As controls, litter mates were injected either with saline or left untreated. At 6-8 weeks of age, the mice were challenged intravenously with 0.1 ml. of a 20 per cent suspension of sheep erythrocytes. The mice were bled from the retro-orbital plexus before and after immunization to obtain serum specimens for determination of serum haemolysins to sheep erythrocytes. At varying intervals after challenge immunization, individual mice were killed, spleens obtained, and cell suspensions prepared<sup>9</sup>. Viability was determined by trypan blue stain, and cell counts were obtained with a haemocytometer. A 0.1 ml. of a suspension of cells containing  $10 \times 10^6$  to  $5 \times 10^5$  nucleated cells per ml. was used for pouring agar plates essentially as described by Jerne *et al.*<sup>10,11</sup>. In brief, 0.1 ml. of the test spleen cell suspension was added to 2.0 ml. of melted 0.7 per cent Noble agar containing 0.1 ml. of a 10 per cent suspension of freshly washed sheep erythrocytes and 1.0 mg DEAE. This mixture was carefully layered over a previously prepared 3-mm thick layer of agar in a 100-mm diameter Petri plate. After the upper cell-agar layer had solidified, the plates were incubated for 1 h at 37° C. The plates were then treated with 5.0 ml. of a 1:10 dilution of fresh guinea-pig complement and incubated for an additional 30 min at 37° C. Following this incubation, zones of haemolysis could be readily seen against the light pink background of unlysed erythrocytes, indicating lymphoid cells which had secreted haemolysins to sheep red blood cells<sup>10,11</sup>.

Table 1 indicates the results observed after plating lymphoid cell suspensions obtained from mice immun-

ized at 6 weeks of age and either previously untreated or injected with sheep erythrocytes at birth and twice weekly thereafter. Whereas approximately 1,200–1,500 antibody plaques were formed per million viable nucleated lymphoid cells from control immunized mice, fewer than 50 plaques were formed with the same number of spleen cells from mice injected with sheep erythrocytes from birth to the fifth week of age. The mean peak haemolysin titres of immune control mice averaged 1:450. Haemolysin titres of mice tolerant to sheep red blood cells averaged 1:60.

Table 1. SERUM HAEMOLYSIN TITRES AND NUMBER OF HAEMOLYTIC PLAQUES FORMED WITH SPLEEN CELL SUSPENSIONS FROM CONTROL AND TOLERANT MICE BEFORE AND AFTER IMMUNIZATION WITH SHEEP ERYTHROCYTES

\* Injected intraperitoneally at birth and twice weekly thereafter for 5 weeks with 0.1 ml. of 20 per cent suspension washed sheep erythrocytes.

† Injected intravenously at 6 weeks of age with 0.1 ml. sheep erythrocytes.

Table 2 indicates mean serum titres and number of haemolytic plaques formed per million spleen cells from control and tolerant animals immunized at several age intervals. All mice injected with sheep erythrocytes at birth and periodically thereafter exhibited markedly depressed antibody titres and plaque counts in comparison to controls. Maximum depression of plaque counts was observed with mice challenged with sheep red blood cells 1–2 weeks following cessation of the tolerance-inducing injections of sheep erythrocytes. An interval of several weeks between the last tolerance-maintaining red blood cell injection and the intravenous immunization resulted in increased plaque counts and higher haemolysin titres (Table 2).

Table 2. SERUM HAEMOLYSIN TITRES AND ANTIBODY PLAQUE FORMATION BY SPLEEN CELL SUSPENSIONS FROM TOLERANT AND CONTROL MICE IMMUNIZED WITH SHEEP ERYTHROCYTES AT VARYING AGES

\* Injected intraperitoneally with sheep erythrocytes at birth and twice weekly thereafter for 5 weeks.

† Injected intravenously with sheep erythrocytes at age indicated.

‡ Spleens obtained for antibody plaque assay four days after challenge immunization.

Although there was a marked difference in the number of plaque-forming cells in suspensions of spleen cells from normal and mice tolerant to sheep red blood cells following immunization, the relative sizes of individual plaques were similar. There was no indication of reduced haemolysin secretion activity by individual cells from the tolerant mice. The only discernible difference between control and tolerant mice was in the number of plaques formed per million viable nucleated spleen cells. In addition, mice rendered tolerant to *Shigella* micro-organisms at birth responded normally with haemolysin formation and antibody plaque production when immunized with sheep red blood cells<sup>13</sup>.

These results demonstrate that injection of mice from birth with relatively large quantities of foreign erythrocytes markedly suppresses not only their capability of forming circulating haemolysins, but also suppresses the absolute number of lymphoid cells capable of forming localized zones of haemolysis in agar. Such marked inhibition of plaque-forming ability persisted at least 2–3 weeks following cessation of red blood cell injection. In further experiments<sup>13</sup>, it has been observed that tissue culture suspensions of spleen cells from tolerant and from normal mice also differ markedly in ability to form antibody plaques. Suspensions of lymphoid cells from normal animals immunized with sheep erythrocytes readily form plaques following incubation in tissue culture medium for a period of 1–10 days. Similar suspensions from tolerant animals are much less capable of forming plaques either initially or following incubation in tissue culture medium for a period up to 10–15 days<sup>12</sup>.

The results of these experiments support the belief that specific antibody-forming cells are absent or in low numbers in lymphoid tissue of animals exhibiting a specific acquired tolerance to non-living antigens. It seems unlikely that low post-challenge haemagglutinin titres in mice rendered tolerant to sheep erythrocytes are due to suppressed antibody formation by many cells or due to rapid elimination of normal levels of antibody bound to 'excess' antigen. Similarity in size of individual plaques from tolerant and control mice suggests that individual cells competent to make haemolysins in tolerant animals form antibody similar in quantity to amounts formed by 'normal' cells in control animals.

### Immunoglobulin-levels in Mice undergoing Graft-versus-host Reaction

It is generally admitted that mice undergoing graft-versus-host reaction reveal diminished immunological competence. In particular, the antibody production following antigenic challenge is known to be depressed<sup>1–3</sup>, although there is little conclusive evidence concerning the behaviour of immunoglobulins<sup>4,5</sup>. This particular aspect of the graft-versus-host reaction has been examined by us.

Adult (C57BL × CBA)<sub>F</sub><sub>1</sub> hybrid mice of both sexes were injected intravenously with 30 × 10<sup>6</sup> spleen cells from C57BL donors. Donors and recipients were matched according to sex. Control animals received (C57BL × CBA)<sub>F</sub><sub>1</sub> hybrid cells, using the same technical procedure. A semi-quantitative dosage of immunoglobulins was performed by the micro-modification of the Ouchterlony technique<sup>6</sup>, using specific antisera prepared against purified immunoglobulin fractions of mice<sup>7</sup>. Thus, the three immunoglobulins (IgG, IgA and IgM) could be

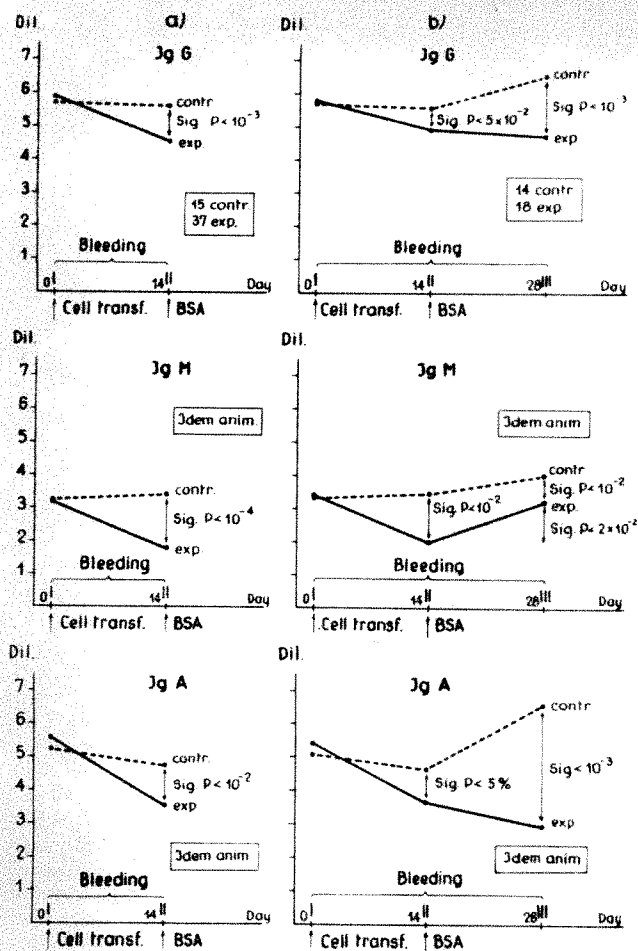

Fig. 1. Immunoglobulin-levels in experimental and control animals

evaluated separately. Total protein values were determined as well, using Folin's method<sup>8</sup>.

Anti-bovine serum albumin antibodies were titrated by passive haemagglutination<sup>9</sup>.

The first signs of the graft-versus-host reaction could be observed at the end of the first week after cell transfer. At the end of the second week the syndrome was well established as judged from the decrease in body-weight (10–20 per cent) and the drop of both total leucocyte and lymphocyte counts (50–70 per cent) with respect to initial values. Simultaneously the levels of all the three immunoglobulins were significantly reduced as compared with initial values and simultaneous control values of animals treated with hybrid cells (Fig. 1). At day 14 after the cell transfer, the mice were stimulated with 50γ of bovine serum albumin, in complete Freund's adjuvant, injected into both hind pads. At the end of the third week the mortality rates were 61 per cent; all control animals were in a perfectly healthy condition. The surviving experimental animals checked at day 28 presented a progressive decrease of the IgG and the IgA globulins, but a significant increase of the IgM fraction was recorded. Control animals displayed a significant rise in all the three Ig fractions (Fig. 1b). Although a drop in total protein values was recorded during the 4 weeks following cell transfer, this drop affected both experimental and control animals in a similar manner and could be attributed to successive bleedings. Anti-bovine serum albumin antibodies, as examined by the passive haemagglutination method 14 days after challenge, were greatly depressed in the experimental group (Table 1). It was further observed that animals undergoing the graft-versus-host reaction, as compared with controls, developed a significantly

lesser local inflammatory reaction at the site of bovine serum albumin plus Freund's adjuvant injection. The reading of reactions was scaled from 0 to +++; results are given in Table 2.

Table 1. PASSIVE HAEMAGGLUTINATION STUDY FOR PRESENCE OF ANTI-BSA ANTIBODIES AT DAY 14 AFTER IMMUNIZATION WITH BOVINE SERUM ALBUMIN

Table 2. LOCAL INFLAMMATORY REACTIONS AFTER THE INJECTION OF BOVINE SERUM ALBUMIN WITH FREUND'S ADJUVANT

Intensity	Exp.	Contr.	Total
0	8	0	8
+	7	3	10
++	5	17	22
+++	1	15	16
Total	21	35	56

$\chi^2 = 26.55$ ,  $P < 10^{-3}$ .

(1) In the course of the acute phase of the graft-versus-host reaction in adult non-irradiated mice a drop in the levels of all three immunoglobulins was observed. The decrease of IgG and IgA values continues in mice surviving the acute phase of the reaction despite antigenic stimulation, although the IgM level tends to rise again and reaches almost initial values.

(2) The antibody response against bovine serum albumin was significantly depressed in animals undergoing the graft-versus-host reaction.

(3) Animals undergoing the graft-versus-host reaction are less susceptible than controls to local inflammatory reactions to a protein antigen incorporated in Freund's adjuvant.

(4) Our observations are in agreement with the poor immunological reactivity generally observed in animals undergoing graft-versus-host reactions.

It seems likely that the reduction of immunoglobulin-levels, of antibody production and of the local inflammatory reactions plays an important part in the establishment of the clinical image of the graft-versus-host reaction.

We thank Prof. P. Grabar, Dr. G. A. Voisin and Dr. P. Burtin for their advice and Mrs. Jeanine Schaffner and Mr. Claude Bernard for their assistance.

**Addendum.** We have examined three immunoglobulins without having considered a recent work of Fahey *et al.*<sup>10,11</sup> showing the existence in mice of a fourth immunoglobulin, which is assimilated by these authors to a  $\beta_2$  A globulin. The protein which we have called IgA corresponds to Fahey's  $\gamma_1$  7 S globulin; the one called by us IgG should correspond to the  $\gamma_2$  7 S globulins.

## RADIOBIOLOGY

Effect of X-ray Dose on the Growth Rate and Delay of the First Post-irradiation Division in a Strain of *Paramecium aurelia*

*Paramecium* is particularly useful in the investigation of the effects of radiation on growth and division. Its size and moderately long generation-time permit accurate accounting of growth. Kimball, Geckler and Gaither<sup>1</sup> have reported an extensive investigation of division effects induced by mustards, ultra-violet light and X-rays on *Paramecium aurelia* and *Paramecium caudatum*. The action of ultra-violet light they observed is rather complex and is in general accord with the action of this agent on a number of protozoa<sup>2-4</sup> (including my investigations<sup>5,6</sup>). However, a series of X-ray experiments has shown some differences from the type of division effects observed by Kimball *et al.* in X-irradiated *Paramecium aurelia*, perhaps because a different strain was used.

This strain of *Paramecium aurelia* was isolated in Texas in 1960 and has been grown as a stock culture since then. Test animals were always grown as isolates in depression slides. Growth was in bacterized lettuce medium prepared in the manner suggested by Sonneborn<sup>7</sup> with *E. coli* as the food bacteria; the strain of *E. coli* was isolated locally. All growth was at room temperature,  $24.5^\circ \pm 1.5^\circ \text{C}$ .

Log phase animals were irradiated with X-rays from a Picker Vangard 250 X-ray machine at 43 krad/min (half value layer, 0.5 mm Al). Dosimetry was carried out with a ferrous sulphate chemical dosimeter using the parameters suggested by Shalek, Sinclair and Calkins<sup>8</sup>. Animals were concentrated by centrifugation to approximately 500–2,000/ml. and a 2-ml. sample was irradiated. No specific radical scavenger such as broth was added to the medium before irradiation; the addition of broth to cultures leads to complications because it promotes an excessive bacterial growth harmful to the protozoa. The animals were irradiated to a desired dose-level, the machine was stopped, an amount of unirradiated medium equal to the sample was added and, after thorough mixing using a transfer pipette, a sample was removed. The X-ray machine was then started and additional doses were given. The samples were diluted with a small amount

Fig. 1. Log-linear plot of increase in average numbers of X-irradiated paramecia as a function of post-irradiation time. Lines are fitted through the points 'by eye'; numbers at the top of various lines indicate X-ray doses in min at 43 krad/min. Actual numbers (not logarithms) are indicated on the vertical axis

Fig. 2. Idealized plot of growth following irradiation. The two parameters (*C* and *K*) described in the text are indicated. Actual numbers (not logarithms) are indicated on the vertical axis

of fresh medium and within 1 h of irradiation single animals were isolated from the irradiated samples into depressions containing approximately 4 drops of medium.

The isolated animals were counted at intervals suitable for the determination of growth rate. Counts on control animals, which continued to grow with negligible delay on isolation, were made at 4- to 10-h intervals until the depressions held a large population. The maximum population a depression will support depends on the food supply, and with the amount of medium used populations ordinarily reached 32–100 animals before divisions completely stopped. Growth to 16 animals was used as the criterion of survival and counts were not necessary after a line descending from an isolated animal reached this number. X-irradiated animals which resumed division continued, with only rare exceptions, to grow to the limit imposed by the food available.

Fig. 1 is a plot of the average number of animals in a depression as a function of time following various X-ray doses. This figure is taken from one particular experiment but it is typical of a number of such experiments. Certain aspects of the response to X-irradiation are clearly illustrated in this figure. The X-rays have produced a progressive delay of the first division following the exposure. When growth does resume, and for the first four divisions after the resumption, the rate of growth of the population is constant within the resolution of the method of growth rate measurement used. It can also be seen in Fig. 1 that the growth rate is progressively reduced with increasing X-ray dose.

The growth of each surviving line descending from an isolated animal has been analysed in terms of a model using two parameters illustrated in Fig. 2. According to the model, when growth is resumed after irradiation it will be at a constant rate for the isolated animals and all their progeny. This type of growth would, in fact, be stepwise because if all progeny grew at the same rate a perfectly synchronized culture would descend from a single animal. The growth rate (measured as 1/doubling time) could be measured by determining the time between a point on one step of the growth curve and the same point on the next step, for example, the time between separation of an animal into two daughters and the separation of those daughters into four animals. The reference time in the cycle could be taken anywhere during the cycle, but division of animals is the only point which can conveniently be recognized, without using procedures which stop further observation.

The growth rate could be determined as indicated here by observations of the exact interval between divisions of isolated animals; however, the number of observations required for growth rate determinations in this manner would impose a severe limitation on the scope of the investigation. Instead, the growth rate of isolated lines has been determined by fitting values of  $K$  and  $C$  to the observed data on increase of numbers. The equation

$$\ln_2 \frac{N}{N_0} = K(t - C)$$

is assumed to be the mathematical relation of increase in numbers with time. In the equation  $N$  is the observed number of animals,  $\ln_2$  is log to the base 2,  $K$  is the growth rate,  $t$  is the elapsed time from the starting point (where  $N = N_0$ ). This equation would accurately represent the growth of a large random phase culture, but deviations are to be expected for small numbers of animals which increase in numbers in a discontinuous manner. The parameter  $C$  will, in small populations, depend on the average amount of the growth cycle completed when the animals are isolated; the effects of radiation on the resumption of growth, as shown by Fig. 1, can also be manifest by the constant  $C$ .

If observations of growth of isolated animals were made many times during each growth cycle (which was not the case) then the best fit of the data, using the model equation, would pass through the centre of the growth steps. Observations were made without any relation to the growth cycle and are observed to be at random locations on the steps. Thus large errors in growth rate determinations for single animals can occur but, assuming random errors, by combining data on a large number of isolated animals an accurate average growth rate can be determined.

Since high-radiation doses can produce quite long delays before growth resumes, and the inclusion of a large number of observations of a single animal (before growth resumed) would tend to reduce the apparent growth rate, counts before the first post-irradiation division were not used for growth rate or delay determinations. It was also observed that, under the conditions of the experiment, growth began to slow after 16 animals were present in a depression (the growth rate of the animals began to be limited by the available food), so the data on growth were not used after this. With these limitations in mind it is obvious that the data presented concern only the first four post-irradiation divisions; effects on growth rate after extended periods of growth have not been investigated.

Parameters  $C$  and  $K$  were determined which best fit the counts of each surviving line descending from a single animal. All animals in an experiment receiving the same treatment were then analysed together and the standard errors of the parameters  $C$  and  $K$  were calculated. The actual computations were done on an IBM 1410 computer using a special programme prepared by Dr. Alan Ross and Mr. Stuart Riley of this Institution.

Fig. 3 shows the relation of radiation dose to growth rate  $K$ . Results from several experiments are plotted on this figure. The standard errors for the points are indicated by the bars. Data from two experiments which seem to show the trend of response most clearly are plotted. Data from a number of other experiments are consistent with the effects shown in the various figures.

Fig. 4 is a plot of the delay of resumption of growth induced by various radiation doses, that is, values of  $C$  for the irradiated animals minus the  $C$  value for the controls, plotted against the square of the dose. The two experiments are again shown by different symbols and the bars indicate standard errors.

Fig. 3 shows that, in *Paramecium aurelia*, recovery from some aspects of X-ray damage is not complete by the time of first division. The radiation-induced depression of growth rate continues for a number of early divisions. The persistence of the effect suggests it is not

Fig. 3. A plot of growth rate (Parameter  $K$ ) as a function of X-ray dose. Two different experiments are shown by the different symbols. Bars indicate standard errors and the lines are drawn through the points 'by eye'.

Fig. 4. A plot of the radiation-induced delay of division (Parameter  $C_{\text{irradiated}}$  minus  $C_{\text{control}}$ ) as a function of the dose squared. Symbols indicate results from the same two experiments as in Fig. 3. Bars indicate standard errors and the line is drawn 'by eye'.

merely destruction of some metabolite but probably a depression of the synthetic capacity of the irradiated animals inherited for a few generations at least. The linear relation between depression of growth and dose is amenable to many hypotheses regarding the nature of the X-ray-induced lesion. One interpretation which seems to fit the data is that the growth is depressed by lesions which are equivalent to mutations in the macronucleus. Information from these damaged DNA molecules would not function properly, but because of the redundant nature of the information in the macronucleus the undamaged duplicate information would permit growth at a reduced rate. Since division of the macronucleus is not perfectly regular, individuals with fewer mutations could occur and show an increased growth rate, representing partial recovery.

The dependence of division delay on the square of the dose is highly indicative of a situation where two lesions interact. Experiments with fractionated doses, to be reported elsewhere, should give an indication of the stability of such lesions if this is the correct interpretation. An interpretation suggested by the dose-delay relation is that a pair of X-ray-induced lesions in the macronucleus interact to cause cross-linkage of DNA molecules; the number of these cross-linkages would depend on the square of the dose. A mechanism for removing cross-linkages would be required before normal growth and

division could be resumed. The time to restore the DNA to its original condition might then be expected to depend on the extent of cross-linkage and thus on the dose squared.

The experiments reported here are not sufficiently definitive to rule out many alternative explanations to those proposed, but the relations between dose and response do suggest hypotheses susceptible to test by experiment.

### A Method for reacting Submicrogram Quantities of Radioactive Substances; Observations on the Preparation of [<sup>131</sup>I]-Iodotyrosines of Very High Specific Activities

We described recently a method of preparation of [<sup>131</sup>I]-iodotyrosines of very high specific activity<sup>1,2</sup>. Further work has shown a considerable difference in the specific activities of these substances obtained in a number of iodinations though the experimental conditions were kept as nearly identical as possible.

Eighty-nine iodinations were carried out with thirty-six different batches of [<sup>131</sup>I]-iodine (Radiochemical Centre, Amersham, Code No. IBS.3) by the method described in our paper<sup>1</sup>. The addition of the various solutions into the reaction flask (1.00-ml. 'E-MIL' volumetric flask) was done with Hamilton syringes and micropipettes. However, even using the same batch of <sup>131</sup>I in a number of successive experiments performed in the course of an hour, the specific activities of the reaction products varied considerably. For example, eleven successive iodinations using 0.09 µg of L-tyrosine from the same standard solution gave monoiodotyrosines with specific activities varying between 0.3 and 1.7 c./µmole, while the specific activities of the di-iodotyrosines varied between 0.6-3.4 c./µmole. In another series of four iodinations, using 0.05 µg of L-tyrosine, the specific activities of di-iodotyrosines varied between 1.3 and 2.5 c./µmole.

We noticed that it was very difficult to discharge the small volumes (10-25 µl.) of successive reactants so near each other that they mixed thoroughly with sufficient speed, especially as the reactions with these small amounts of substance are completed in a few seconds. To obviate these difficulties we proceeded as follows: a Hamilton syringe (total capacity 100 µl.) was linked through a specially adjusted connector (Tully Anaesthetic Co.; Luke's female Luerlock gland connexion No. 2) to a 250-mm length of polytetrafluorethylene tubing (A.E.I. Plastics, Ltd., size 0.023 in. internal diameter, wall thickness 0.010 in.; type TWT 24). The connector carried on one end a soldered-in Luer fitting for connecting the syringe; on the other end of the connector the polytetrafluorethylene tubing was threaded through a tight-fitting hole in a piece of rubber which was then compressed by the movement of a screw of the connector.

Moving the syringe, 25 µl. of the chloramine-T solution were first sucked into the tubing, followed by 5 µl. of air;

Table 1

	µg L-Tyrosine	<sup>131</sup> I-MIT (c./µmole)	<sup>131</sup> I-DIT (c./µmole)
First set	0.04	1.80	3.54
	0.20	1.61	3.20
	1.00	0.29	0.58
Second set	0.04	1.99	3.97
	0.18	1.69	3.38
	0.91	0.29	0.58
Third set	0.04	2.26	4.51
	0.18	1.74	3.48
	0.91	0.33	0.65

then 25 µl. of the L-tyrosine solution were sucked into the tubing followed by 5 µl. of air; and 20-25 µl. of radioactive iodine solution (100 µl. = approx. 20 mc.) were sucked into the same tube, again followed by 5 µl. of air. In this way all the reactants were contained in the polytetrafluorethylene tube, separated from each other by long air bubbles, and the length of tubing was such that the solutions were far enough from the syringe to prevent contamination.

To carry out the reaction, the tubing was firmly introduced to the bottom of the reaction vessel, and the reactants expelled at a steady rate. In this way they were not only discharged into the same place within the reaction vessel, but the succeeding air bubbles mixed the solutions thoroughly. To terminate the reaction the metabisulphite solution (100 µl.) was added through another length of tubing. The relatively inexpensive polytetrafluorethylene tubing was discarded after use.

Three sets of iodinations performed in three succeeding weeks, each set using a different batch of iodine-131, gave the results shown in Table 1.

These results form part of an investigation into the occurrence of iodotyrosines in human plasma. We thank the Medical Research Council for a grant in support of this work.

## BIOLOGY

### Anatomical Adaptations for Olfaction in the Snow Petrel

THE accompanying photographs show the exceptional development of the olfactory apparatus of the snow petrel, *Pagodroma nivea*. As we have previously pointed out<sup>1</sup>, all Procellariiformes (tube-nosed birds, or tubinares) have great olfactory equipment. The snow petrel, however, is the peer of them all. In four other tube-nosed species, Dr. Stanley Cobb<sup>2</sup> has found that the ratio of the diameter of the olfactory bulb to the diameter of the hemispheres is 29-30 per cent. He measured the snow petrel shown in Fig. 2 and found the corresponding ratio to be 34 per cent. Not only is the receptor surface area of tubinares much enlarged by an additional concha which arises from the septum and interdigitates with the olfactory concha proper (Fig. 2), but the whole nasal fossa is apparently engineered for optimum olfactory reception. Using the snow petrel as a model, I would like to point out two structures in the entry area of the tubinarial fossa which I believe are directly concerned with olfaction, yet the function of which in this respect has been obscured by having other functions attributed to them in the literature. These are the anterior concha and the anterior valve.

The tubinarial anterior concha is rather small, but its position and shape render it important in distributing inspired air and segregating the out-flowing lateral nasal gland fluids from the airstreams. Its position at two

vertical levels is shown in Fig. 3. A twist in its course, not demonstrable in this plane, directs a medio-dorsal air-stream on to the olfactory surfaces and a ventral stream over the respiratory area and into the pharynx. The concha fulfils all the criteria of the anterior concha of the Aves, yet has been described as a structure peculiar to tubinares, and has been variously called a 'nasal flange', a 'paraseptal process'<sup>3</sup> and a 'lamina vestibuli'<sup>4</sup>.

The anterior valve is, I believe, entirely concerned with keeping water off the olfactory organ of pelagic diving birds. It is as prominent a structure in other pelagic diving species as it is in the tubinares. Two quite different functions have been attributed to it. Portmann<sup>5</sup>, proposing that birds smell via the choanae, says: "In general the plan of the nasal fossae prevents the direct entrance of the respiratory (air) current into the olfactory region. In the tubinares this entrance is even closed by a special membrane, a sort of valve which permits only the passage of the expiratory current". Mangold<sup>6</sup> suggests that the anterior valve in 'dynamic gliders', such as the tube-nosed birds, might be an air-velocity sense organ or air-pressure indicator, and illustrates the idea with clear

Fig. 1. Sagittal section of snow petrel nasal fossa showing relative size of medial surface of main olfactory concha. Note size of stem of concha. B, olfactory bulb; OC, olfactory concha. Numbered lines indicate level of vertical sections in Figs. 2-4

but inaccurate drawings of fulmar valves, which have been widely copied. However, none of the more than sixty large or small gliding, or other, land species in our collection has anterior valves except the diving kingfishers, the well-developed ones of which have apparently been acquired by parallel evolution<sup>7,8</sup>. In all species which have them, the crescent-shaped valves are formed by a single fold of the most anterior mucous epithelium; the free border faces the nostrils and the blind end is firmly anchored to the mucoperiosteum. In freshly killed birds, and in histological sections through the valves, it is apparent that in the 'resting' state the valves lie close against the septum, and that they tend to adhere to the septum by means of the adjacent (valve-septal) mucous blankets. It is suggested that this is the case when the birds are on land or are flying, and that the air passages are then fully open for olfaction and respiration (Fig. 4a). When the birds dive, however, the valves would be opened by the force of the water (Fig. 4b). The olfactory mucosae would thus be protected from the abrasive impact of seawater, while the respiratory epithelium, which carries the trigeminal free nerve endings so important to pelagic animals<sup>9</sup>, remains open to the water. Bits of shale or seaweed are often caught in the valves of pelagic divers, or stuck on the respiratory conchae, but I have never yet found debris of any kind on the olfactory membranes. I did some crude tests with fresh herring gull heads sectioned

just at valve level and found that the valves remained adherent to the septum during successive quick mock airdives, but that they opened instantly if a submerged head was pulled gently upward in a tank, nose first.

Dr. Robert Cushman Murphy informs me that snow petrels feed on fish to a greater extent than do any other antarctic petrels, and that most of their fishing is done at night in the small channels of ice floes. Since in tubinares the olfactory bulb is much larger than in most other birds, since the nasal apparatus apparently ensures optimum olfaction, and since extraordinary feats of food-finding have been described for several species<sup>1</sup>, it is hard to escape the conclusion that in the Procellariiformes olfaction is a dominant sense and that food-finding is one of the functions of that sense. It is worth reiterating, however, that the olfactory epithelium is also strongly developed in species which lack olfactory conchae, or lack nostrils, or both, as well as in species the habits of which suggest olfactory behaviour other than food-finding<sup>2</sup>.

I thank Mr. Robin Woods for the pair of snow petrels used in this investigation, obtained from the waters of Signy Island in the South Orkneys in co-operation with the Falkland Islands Dependency Service, Dr. Cobb for his collaboration and advice, and Dr. Murphy for permission to quote his correspondence.

These investigations are supported by grant GB 393 of the National Science Foundation.

### Giant Epiphyses in a Ross Seal

THE ROSS SEAL (*Ommatophoca rossi*) is a relatively little-known animal and it was not until recently, when the British Museum (Natural History) received two frozen specimens from the British Antarctic Survey, that any detailed investigation of it could be attempted. Several curious characters have been noted in the first of these seals to be dissected, including a peculiarity of the flippers.

The elongated, rather delphinoid shape of the fore flippers is brought about by an increase in length of the first digit and a decrease in length of the fifth. This is mainly achieved by means common to other members of the Lobodontini, and to the Otariidae—the metacarpal and first phalanx of the first digit are elongated, while the second phalanx of the fifth digit is reduced. This tendency to increase the length of the flipper has been carried further in *Ommatophoca* by an unusual means, not previously recorded. An X-ray photograph of the fore flipper of one frozen animal, a female, shows, by the presence of unfused epiphyses, that the seal was not yet physically mature. The epiphyses on all the bones of the manus, except those of the terminal phalanges, are unremarkable and 'normal' in their dimensions. Their approximate lengths vary between 7 and 10 mm, and their proportion to the shaft is about 10–16 per cent. The epiphyses on the terminal phalanges are, however, very noticeable both for their size and shape. Their lengths range between 7 and 24 mm, that on the first digit being the largest, and their proportions to the rest of the bone between 40 and 82 per cent. As can be seen from Fig. 1a,

(a)

(b)

Fig. 1. Radiographs of Ross Seal (a) fore and (b) hind flipper

this epiphysis on the first digit is very nearly as long as the shaft, and its size and its rectangular shape are quite unusual. Those on the other terminal phalanges are also much larger than might be expected. Skeletons of *Ommatophoca* are rare in collections, but skins brought back by some of the early Antarctic expeditions still have the terminal phalanges *in situ*. X-ray photographs have shown that in every specimen so far available these giant epiphyses can be seen.

Tips of seal flippers of appropriately immature animals are not easy to find, but an examination has been made of the fore flippers of as many phocid seals as possible. Only in the Leopard Seal (*Hydrurga leptonyx*) are there comparable epiphyses, although they are relatively not so big as in the Ross Seal.

On the terminal phalanges of the hind flippers of *Ommatophoca* (Fig. 1b) similar large square or rectangular epiphyses are present, that on the first digit being most spectacular with a length of 33 mm, the rest of the phalanx being 44 mm long. Large but less peculiar epiphyses are present in *Hydrurga*. There is some evidence that there are unusually large epiphyses on the terminal phalanx of the first digit of the hind flippers in such northern phocids as *Pagophilus* and *Cystophora*.

The elongation of these epiphyses, particularly that of the terminal phalanx of the first digit, which involves elongation of the digit as a whole, probably has some bearing on the animal's superior powers of aquatic locomotion. It may be significant that the fore flipper of *Ommatophoca*, the most specialized phocid, exhibits a character usually found (and to a much lesser degree of development) only in the hind flippers of less-adapted phocids. Some other characters, to be reported later, have a similar distribution.

### Early European Description of an Australian Mammal

In the account of an early description of an Australian mammal given by Dr. Wilma George<sup>1</sup> several suggestions were made as to the possible identity of this animal. No definite conclusion was reached and *Thylogale stigmatica*, *Hypsiprymnodon moschatus* and *Uromys caudimaculatus* were all offered as possible species which might satisfy the original description.

One particular group of marsupials which does not appear to have been considered in this problem is the genus *Phalanger* containing the cuscuses. Seven features were tabulated which were derived from the original description by Prado and then each species was scored for closeness of fit. A maximum of 5 points out of a possible 7 was scored by both *Thylogale stigmatica* and *Hypsiprymnodon moschatus*.

If similar scoring is applied to species of *Phalanger*, a better result is obtained.

Cuscuses are widely distributed in south-east New Guinea<sup>2</sup>, they have a strong musky odour from which the name castor could be derived and they have a naked scaly prehensile tail. They feed mainly on leaves and are eaten extensively by the native people of New Guinea<sup>3</sup>. The descriptions of the testicles given by Prado which "hung from a nerve like a thin cord" would fit the cuscus as well as any other marsupial. This feature alone in the description would seem likely to preclude any group of Australian mammals other than the marsupials, which are characterized by a typically pendulous scrotum. The description of "an animal which is in the shape of a dog, smaller than a greyhound" could be distorted to fit many small or medium sized mammals and would be as equally applicable to a cuscus as to any of the other species listed.

Even if this latter feature were scored zero, some species of *Phalanger* would still rate 6 points out of a possible 7.

Some features in the description are of greater diagnostic value than the remainder and could be given greater emphasis without risk of subjective distortion. These include the scaly tail, pendulous testes and distribution in south-east New Guinea. Only the genus *Phalanger* possesses all these characteristics since *Thylogale* does not

have a scaly tail and *Hypsiprymnodon* is confined to Queensland.

It is therefore probable that the animal described by Prado in 1606 was actually a cuscus, *Phalanger* sp.

B. J. MARLOW

The Australian Museum,  
Sydney.

<sup>1</sup> George, W., *Nature*, **202**, 1130 (1964).

<sup>2</sup> Tate, G. H. H., "The Marsupial Genus *Phalanger*", *Amer. Mus. Novitates*, **1283**, 1 (1945).

<sup>3</sup> Waterhouse, G. R., *Natural History of the Mammalia*, **1**, Marsupialia, 277 (Baillière, London, 1846).

DR. WILMA GEORGE has recently brought to scientific notice what is apparently the earliest known description of an Australo-Papuan mammal and discusses its possible identity<sup>1</sup>. Briefly, in 1606 Don Diego de Prado y Tovar sailed along the southern coast of New Guinea and through Torres Strait, and in his *Relación* described how on the south-eastern coast of New Guinea his party killed an animal "in the shape of a dog smaller than a greyhound, with a bare and scaly tail like that of the snake, and his testicles hang from a nerve like a thin cord; they say that it was a castor, we ate it and it was like venison, its stomach was full of ginger leaves and for that reason we ate it".

George gives equal weight to all the characters listed by Prado and tests the results against a series of Australian and Papuan mammals, the information about them being obtained from standard works. She concludes that the description best fits the musky rat-kangaroo (*Hypsiprymnodon*), but that a wallaby (*Thylogale*) and a rat (*Uromys*) are strong contenders. None of the works listed, however, has the kind of detail necessary for a good analysis of Prado's description. As George remarks there is no reason to doubt the accuracy of the description, and for that and other reasons I cannot appreciate her view that weighting of the various points would lead to difficulties.

A key character is the description of the testes, which George interprets to mean merely 'prominent' or 'evident'. Anyone familiar with living marsupials must be struck by the aptness of Prado's lay description of the suspended pre-penile scrotum of most male marsupials. This is particularly obvious in the Macropodidae. In adult kangaroos of the larger species, the large roughly spherical scrotum hangs several inches below the body by a thin scrotal pedicle. Movement of the scrotum is apparently under conscious control and it is drawn up against the body during such activities as hopping, fighting, and copulating. In death it hangs freely in the extended position. I believe that this part of Prado's description diagnoses his animal as marsupial and removes any of the eutherian rats, such as *Uromys*, from consideration.

Large marsupials with scaly tails which could have been encountered by Prado on the south-eastern coast of New Guinea are two wallabies, *Dorcopsis veterum* (= *muelleri*) and *Thylogale brunii*, and one or two species of cuscuses (genus *Phalanger*). The last-named genus was not considered by George. The distal inch or so of the tail of *Dorcopsis* is scaly and bare of hair but the rest of the tail is well furred. In *Thylogale brunii* and other species of that genus the greater part of the tail is scaly with sparse hair on the sides and somewhat more hair on the upper and lower surfaces. In some specimens of *Thylogale* the hair on the tail is very sparse indeed, perhaps depending on stage of moult or age. The scaly nature and sparseness of hair on the tail of *Thylogale brunii* is well shown by Alston's illustration of this species (under the name of *Macropus lugens*)<sup>2</sup>. The tails of *Phalanger* spp. are naked for two-thirds or more of their length on the ventral surface and approximately half on the dorsal surface and there are large scales on a considerable part of the ventral surface.

It is reasonable to assume that when Prado described his animal as shaped "like a dog smaller than a greyhound" he meant that it resembled a small example of that breed of dog in shape as well as in size. To Europeans seeing macropodids for the first time the comparison in shape with a greyhound is not at all unreasonable. It will be recalled that Captain Cook, when he saw a kangaroo for the first time at Endeavour River, recorded in his journal that it was "the full size of a grey hound and shaped in every respect like one"<sup>1</sup>. *Dorcopsis veterum* and *Thylogale brunii* are slenderly built and have dog-like muzzles and rhinaria, ears roughly proportional in size to those of greyhounds and dark grey short fur. Cuscuses, on the other hand, are short-legged and do not resemble greyhounds in body conformation or shape of head. Moreover, they have extremely short ears and woolly fur. The male of the widespread *P. maculatus* is strikingly blotched reddish-brown and cream, while the forms of the other widespread species group, *P. orientalis*, are brown or dark grey. One would think that had Prado seen a cuscus he would have compared it to some other breed of dog or a well-known European animal.

George's choice of *Hypsiprymnodon* does not fit well on the score of size as it is a diminutive creature with a head-and-body length of little more than 1 ft. and weighs only about 1 lb. Moreover, there is no recent or fossil evidence that it ever occurred in New Guinea or even the northern part of Cape York Peninsula, or its offshore islands where some authorities claim that Prado touched.

The reason why Prado's animal was called a castor may have been because of a smell it emitted, or the fact that it had gnawing teeth or perhaps even because it had a scaly tail. George apparently does not realize that many male marsupials including some species at least of macropodids and phalangerids have strong characteristic odours. Of the mammals known to Europeans the teeth of macropodid and phalangerid marsupials have a marked superficial resemblance to those of rodents, because of the single pair of procumbent lower incisors, the diastemata between the incisors and cheek teeth, and in most macropodids, the lack of canines. The teeth of diprotodont marsupials were very puzzling to early naturalists, and in some of their classifications these animals were placed in or near the rodents. The unity of the Marsupialia was finally recognized by de Blainville<sup>4</sup>, and it is significant that in his classification he used the name 'Rongeurs' for the subdivision of the marsupials (his "Didelphes Normaux") containing the diprotodonts.

The fact that the stomach of Prado's animal was full of 'ginger leaves' is of no significance and merely indicates a herbivore. Likewise it is of no importance in attempting to determine the nature of the creature that the flesh was eaten and tasted like venison to early seventeenth-century European sailors.

In summary, I believe that Prado's mammal was certainly a marsupial, probably a wallaby and possibly a cuscus; the species that best fits his description is *Thylogale brunii*.

<sup>4</sup> de Blainville, H. M. D., *Bull. Soc. philom.*, Paris, 105 (1816).

Mr. Calaby and Mr. Marlow have added interesting comments towards establishing the identity of Prado's Australasian mammal. I am grateful to them for pointing out the claims of *Phalanger*.

Testing for an association between Prado's description and modern descriptions of likely animals I was particularly concerned not to weight any characteristic more than any other since there is no consistent system for applying such weighting. Inconsistent weighting leads Mr. Calaby and Mr. Marlow to different conclusions. Mr. Calaby gives little weight to the interpretation of the term castor and to the question of edibility but stresses the prominent testicles and the likeness to a small greyhound and the scaly tail. In contrast Mr. Marlow by implication gives little weight to the likeness to a greyhound but stresses the other characteristics.

In spite of being an adherent of the rigorous numerical method of assessing associations of a range of characteristics<sup>1</sup> and, by this method, eliminating the greater part of the Australasian mammal fauna from the discussion, I am prepared to apply at this stage a certain amount of subjective freedom to the final choice. It seems necessary in this case because none of us can examine the specimen we are trying to identify and because we are making a basic assumption that Prado's description is accurate.

If it is accepted that the original method eliminates the outsiders there remain only *Thylogale*, *Hypsiprymnodon* and *Uromys* with the addition of *Phalanger*. A new assessment can be made of these four. One method of weighting is to accept the opinions of those experienced in the study of mammals and of the fauna of the region. I suggest that the opinions of Mr. Calaby, Mr. Marlow and myself are taken into account together with some of the original zoological descriptions<sup>2-6</sup> of the animals and some early explorers' descriptions<sup>7,8</sup>. By doing this, weighting can be applied to each characteristic to a maximum of four points derived from our three opinions and those of either the early describers or the casual explorers.

All are agreed that the prominence of the testicles is a peculiarly marsupial feature and can therefore be weighted more heavily than any of the other qualities. Whether greater weighting should be given to *Thylogale* and *Hypsiprymnodon* than to *Phalanger* in this respect is a difficult decision to take; but, having accepted weighting, I am inclined to weight ruthlessly and score say four for *Thylogale* and *Hypsiprymnodon* and two or three for *Phalanger*, since I believe the thick soft fur makes them less obvious than in the macropodids. *Uromys* does not score.

It is fair to say that all four genera could equally have been eating ginger leaves, and this characteristic can either be eliminated or scored the same for each.

All four genera are presumably edible. Mr. Calaby says it is of no importance, Mr. Marlow that the natives eat cuscuses and it is, therefore, important. There is good evidence for the natives of New Guinea eating cuscuses and a great deal of historical and present-day evidence for Europeans and natives eating and enjoying wallabies and kangaroos. Both Dampier<sup>7</sup> and Cook<sup>8</sup> record that these animals were very good eating, and kangaroo meat is a considerable export to-day. It becomes difficult to know how to score this except by giving two points to *Thylogale* and two to *Phalanger* as being better to eat than the other two, which score only one each.

Their occurrence in south-east New Guinea is an unreliable point since it is not known exactly where Prado was; nevertheless, all except *Hypsiprymnodon* can score one.

I do not agree with Mr. Calaby that the term castor would have been used to describe a type of jaw and dentition which in its general features is common to all rodents. It seems more likely to apply to an odour resembling that of castoreum or castor from the genital glands of the beaver and for which, among other things, the beaver was hunted. Cuscuses and *Hypsiprymnodon* have a strong musky odour, and score two at least on this point. I am aware of Mr. Calaby's point that some

macropodids have strong odours and I attach considerable importance to the possibility of differentiating species of some animals, particularly rodents, by their distinctive odours. However, I cannot find any record of the scents of any of these animals, and would appreciate further information on this point. Failing this factual information no more than one can be scored for *Thylogale*.

We are not agreed on the tail. Mr. Calaby and other authors<sup>2-4</sup> describe the sides of the tail of *Thylogale* as scaly, Mr. Marlow says that *Thylogale* does not have a scaly tail. Reading through the early descriptions of *Thylogale* and *Phalanger* species<sup>2-5</sup>, I conclude that the tails of either of these genera could in some circumstances be called scaly. *Hypsiprymnodon* and *Uromys* certainly have scaly tails so this character can also be eliminated as common to all.

"In the shape of a dog smaller than a greyhound" is a similar description to that given by Dampier to describe a wallaby, and the greyhound analogy was also used by Cook. Although Mr. Calaby and Mr. Marlow disagree on this point I am inclined to weight small greyhound four points in favour of *Thylogale* and one each for *Phalanger* and *Hypsiprymnodon*. *Hypsiprymnodon* only scores one on this round for being too small and more likely to have been described as jerboa-like since this too was a common analogy. *Phalangers* had been described as monkeys by other visitors and it seems difficult to apply a greyhound description to it.

This revised estimate arrived at by ruthless weighting gives a big overall majority to *Thylogale*, twelve, with *Phalanger* eight or nine points, *Hypsiprymnodon* eight, and *Uromys*, with two, out of the running. *Thylogale* was always my favourite competitor so I can be charged with weighting in its favour. Weighting being a matter of opinion and not mathematically determinable in such cases, other authors can apply a different system and arrive at a different answer. In the meantime I think we are all agreed that there is little doubt that Prado's description is at present the earliest European record of a marsupial, and two of us are agreed that the description fits *Thylogale* best. Before making a choice between *T. stigmatica* and *T. brunii* which I considered together in my original report I would like to know whether one of them has a more castor-like odour than the other.

### Germination of *Rosa arvensis*

It appears that dormant rose achenes of many species may be put in the same category as those 'two-year' seeds which require a warm period in the soil to permit disintegration of the coat, followed by a period at low temperature to after-ripen the embryo. On the other hand, Harrison<sup>1</sup> reports that achenes of *R. arvensis* germinated in good numbers in the first year after planting in the autumn under natural conditions. This behaviour appears to be characteristic of members of the section *Synstylae*<sup>2</sup> and also to some extent of *R. rugosa*<sup>3</sup>.

It has been shown<sup>4</sup> that the lack of immediate germination in the achene of *R. arvensis* is not due primarily to the massive pericarp acting as a barrier to the movement of water or gases. That a similar conclusion may be applied to the action of the underlying testa is shown

Table 1. GERMINATION AT 26° C OF SEEDS OF *R. arvensis*

	% Germination after 14 days
Entire seeds (embryo + testa)	10
Cap of testa over radicle removed	20
Only cap of testa left: remainder removed	30
Whole of testa removed	50

by the results in Table 1, obtained by the methods previously described. It thus appears that the mere presence of the whole or part of the testa inhibits germination to some extent.

The dormant achenes of *R. rugosa* contain substances (soluble in water, ethanol and ether) which inhibit the straight growth of *Triticum* coleoptile sections and the germination of *rugosa* embryos<sup>4</sup>. These two tests were therefore used on eluates of the segments of chromatograms run from the acidic fraction (separated on an activated alumina column) of the ether-soluble material present in the diffusate obtained by steeping dormant achenes of *R. arvensis* in 80 per cent ethanol for five days at 2° C. Fig. 1 shows the result of the embryo test. When the embryos in the highly inhibitory eluates from the  $R_F$  segment 0.4-0.5 were then washed for a few minutes in water and returned to a clean germinating dish containing water, 60 per cent germination occurred in the next 24 h; there seems little doubt that the inhibitors were not toxic in the concentrations used here and may be readily leached from the embryo. Since it had also been shown that the dormancy imposed by the testa on the embryo in *R. arvensis* could be alleviated almost completely by soaking the seeds in the kinetin analogue, 6-benzylaminopurine (10 µg/ml.), or to a slightly lesser extent by gibberellic acid (150 µg/ml.), a duplicate experiment was carried out in which the inhibitory segments  $R_F$  0.3-0.4 and 0.4-0.5 were eluted with the purine solution instead of water. Fig. 1 shows that the inhibition was again removed almost completely. The wheat coleoptile, straight-growth assay also showed the presence of inhibitors around the middle of the chromatogram, and they may therefore be compared in some respects with the phenolic inhibitors which Varga<sup>5,6</sup> found in the outer parts of many fruits and equated with the β-inhibitor complex of Bennet-Clark and Kefford<sup>7</sup>.

Fig. 1. The germination after 6 days of naked embryos in eluates from a chromatogram of the acidic fraction of the ether-soluble substances present in an ethanolic diffusate of dormant achenes of *R. arvensis*. Chromatogram run in butanol/ammonia/water: 10/1/1. —, Segments eluted with water; ---, segments  $R_F$  0.3-0.5 from a duplicate chromatogram eluted with 6-benzylaminopurine

Although leaching of the inhibitors from the achenes by soil water probably occurs under natural conditions, there is some evidence<sup>4</sup> that cold-stratified embryos of *R. rugosa* are able to germinate even in the presence of inhibitors from dormant achenes of the same species; it appears likely that the state of the embryo is controlled by the balance between growth-inhibitors and promoters (such as kinins and gibberellins) as well as by the absolute amount of the former.

We thank Dr. C. G. Skinner, of the University of Texas for a gift of 6-benzylaminopurine, and Dr. F. Fajersson of the Plant Breeding Institute, Weibullsholm, for 'Atlé

wheat, and the Royal Society for a grant in support of this work.

### Ammonium Requirement for Embryogenesis in vitro

PREVIOUS work on tissue cultures of the wild carrot has shown that the embryogenesis which occurs in such cultures is not fundamentally different from the same process in the ovule<sup>1,2</sup>. It has also been shown that undifferentiated pro-embryos, sieved from callus, will continue to grow in a disorganized non-polar fashion if they are exposed to a concentration of 2,4-dichlorophenoxyacetic acid (2,4-D) which is higher than 0.1 mg/l. (ref. 3). Lowering the 2,4-D concentration permits histological differentiation and polarized growth to occur. It is thus possible to establish a crude control over the process of embryogenesis by suitable alterations of the 2,4-D concentration. While this technique has provided an experimental system in which the simultaneous development of numerous embryos can be examined, it has provided no information on the morphogenetic factors which initially cause cultured cells to behave as zygotes.

Recently, the relative effectiveness of different nitrogen sources on the growth of a strain of wild carrot callus which was originally derived from storage root phloem was examined. This strain had been in culture for more than one year on a simple medium consisting of minerals, sucrose, vitamins, kinetin, and 2,4-D. It was found that callus grown in the absence of ammonium would not form embryos when transferred afterwards to a medium which would normally permit (by lowering the 2,4-D level) development of any pro-embryos present in the tissue. Phloem-derived tissue will grow indefinitely on nitrate as the sole nitrogen source, with the optimal nitrate concentration about 60 mmoles/l. Addition of as little as 5 mmoles/l. ammonium, while inhibiting growth slightly, permits embryogenesis to occur. Microscopic examination of callus grown exclusively on nitrate nitrogen revealed only single cells and a virtual absence of multicellular structures (Fig. 1a). Examination of the same strain of callus grown on ammonium-containing media revealed numerous multicellular filaments which were recognizable as pro-embryos (Fig. 1b).

In subsequent experiments which were designed to test the validity of this phenomenon with other strains of wild carrot callus, it was found that petiole segments proliferated very slowly if they were placed on a medium containing nitrate as the sole source of nitrogen and 2,4-D as the sole hormone. If ammonium was added to this medium, a healthy rapidly growing callus developed. It was found that addition of kinetin to the medium eliminated the ammonium requirement shown by explanted petiole segments. By using both kinetin (0.5 mg/l.) and 2,4-D (0.5 mg/l.) it was thus possible to obtain petiole callus which grew as well on media containing only nitrate as it did on nitrate plus ammonium.

To test systematically for the presence of pro-embryos in such callus, a method was used which was a modification of techniques previously described<sup>3</sup>. The 45–75  $\mu$  cell fraction from petiole callus (after 60 days in culture) was used to inoculate liquid culture tubes (18 mm  $\times$  150 mm rimless test-tubes sealed with polyethylene) which were

Fig. 1. A, cells from phloem-derived callus which has been grown on a medium containing nitrate as the sole nitrogen source. B, cells and pro-embryos from phloem-derived callus grown on media containing ammonium. Arrows indicate proembryos. C, embryos which formed in rotating liquid cultures inoculated with the cell fraction shown in B. D, normal plantlets from embryos shown in C.

rotated at 2 r.p.m. in a position about 10° from the horizontal. It should be pointed out that in the process of removing this fraction from callus, the cells are washed by approximately one-half litre of fresh medium. The test medium used was the basal medium previously described<sup>3</sup> modified to contain either 60 mmoles/l. potassium nitrate, or 55 mmoles/l. potassium nitrate plus 5 mmoles/l. ammonium chloride. Kinetin was supplied at 10<sup>-3</sup> mg/l. and 2,4-D at 5  $\times$  10<sup>-4</sup> mg/l., levels low enough to permit development of any pro-embryos present in the inoculum to be tested.

The cell fraction obtained from nitrate-grown petiole callus failed to produce embryos in either of the two liquid media (nitrate, or ammonium plus nitrate). In the case of the cell fraction from callus grown on ammonium-containing media, many embryos were observable in the cultures within two weeks of inoculation. Embryos were as numerous in the tubes which contained no ammonium as they were in those with ammonium. While ammonium is thus required for initiation of embryo-genesis in cultured cells, nitrate alone may be sufficient for the further development of pro-embryos in the undifferentiated state (Fig. 1B) to the mature state (Fig. 1C). However, the part played by conditioning of the medium requires investigation. It is possible that young pro-embryos require reduced nitrogen and obtain it in these cultures by absorbing the nitrogen released in various molecular forms by living and dead cells in the suspension. Raghavan and Torrey have recently shown that undifferentiated pro-embryos of *Cattleya*, an orchid, require ammonium. The failure to grow on nitrate was correlated with low nitrate reductase activity<sup>4</sup>.

Fig. 1C is a drop of suspended material taken from a liquid culture tube 13 days after inoculation. These embryos are quite normal. If the embryos are left in the rotating culture tubes longer than 2 weeks, the primary root grows out and mature leaves appear (Fig. 1D). Mature leaves appear in both the presence and absence of ammonium. Growth of the plantlets is definitely slower, however, in the medium lacking ammonium.

A major problem concerns the total failure of pro-embryos to form in the liquid culture tubes which contained ammonium and which received nitrate grown callus. We assume from this fact that new pro-embryos also failed to form in the tubes inoculated with ammonium-grown

petiole callus, and that the embryos found in these tubes developed only from the pro-embryos already present in the inoculum.

Preliminary results, using the phloem-derived callus, indicate that other sources of reduced nitrogen (glutamine, aspartate, a mixture of 14 amino-acids, coconut milk) will not substitute for ammonium.

### Capillary Movement in Fungal Hyphae

SOME years ago I observed<sup>1</sup> capillary movement in the hyphae of *Mucor mucedo*; the phenomenon was not photographed at the time and subsequent attempts to repeat the observation were unsuccessful. Recently, however, the observation has been repeated, in fungi cultivated on dishes of sugar-agar. Capillary movement was observed after the addition of a drop of guinea-pig blood to the culture medium, but it is uncertain whether the relation between the observation and the addition of blood was causal or merely fortuitous.

Serial photomicrographs have been prepared, demonstrating the phenomenon, and Fig. 1 shows part of such a series. The movement of the hyphal contents was slow but continuous; displacement in the large hypha shown in the photograph was from left to right and the rate of flow was variable. Transport from 'A' to 'A'', as shown in Fig. 1, took from 0.25 to 10 min. Movement within the smaller hyphae was towards the larger one.

The stream carried with it the protoplasts<sup>2</sup> and smaller particles, and movement was continuous over a period, usually of hours, but in one case for several days. The oval or lozenge-shaped segments seen in the photographs

are broken up or deformed from time to time, especially as they enter the large hypha from a tributary, somewhat in the way that erythrocytes may be deformed in capillary transport in animals<sup>3</sup>.

### Inhibition of the Perfect Stage of *Venturia inaequalis* (Cooke) Wint., by Urea

EPIDEMICS of apple scab (*Venturia inaequalis*) originate from ascospores discharged from perithecia present on over-wintered leaves on the ground. Hutton<sup>1</sup> has shown that post-harvest pre-leaf-fall applications of organo-mercurial compounds greatly improved the level of disease control in that they suppressed perithecial formation and hence reduced the amount of ascospore inoculum in the following spring.

Recently there has been growing interest in the use of post-harvest pre-leaf-fall urea sprays as a means of supplying nitrogen to fruit trees<sup>2</sup>. As *in vitro* investigations had suggested that excess nitrogen could suppress perithecial formation<sup>3</sup>, we studied the effects of urea on the development of *Venturia inaequalis* in overwintering leaves.

In October 1963 scab-infected apple plants (clone M.III) were sprayed in the field with either 5 per cent or 2 per cent urea solutions. 48 h later samples of 200 leaves from each treatment, and a control sample from trees sprayed with water, were placed in 14 × 14 mesh nylon envelopes and allowed to overwinter in an exposed situation on the ground. Analysis of leaves immediately after collection showed the percentage dry weight of nitrogen to have increased from 1.81 to 2.06 with 2 per cent urea and to 2.49 with 5 per cent urea. In November further leaf samples were taken from non-treated M.III plants and from the scion variety 'Granny Smith', dipped in 5 per cent urea or in water (control) and then similarly overwintered. All urea solutions contained 0.01 per cent of the wetting agent 'Agral LN' which has been shown to be biologically inactive in the context of the present work.

During the next 4 months, observations were made on the state of the leaves and, at intervals, random samples of 10 dipped and 10 non-treated M.III leaves were tested for microbial activity. Two 1-cm. disks were cut from each leaf and the bulk samples of 20 disks macerated in 10 ml. of sterile distilled water in a Measuring and Scientific Equipment microhomogenizer for 4 min. After allowing large pieces of leaf debris to settle, 1 ml. of the supernatant liquid was withdrawn and suitable dilutions plated into nutrient agar containing 5 per cent sucrose. Bacterial colonies were counted after 3 days at 25° C.

The 5 per cent urea had a noticeable effect on the decomposition of the leaves. Five weeks after treatment the laminae of many of the sprayed leaves had partially or completely disappeared, leaving a veinal skeleton. The dipped leaves remained intact until the following spring, but were observed to be a darker brown than the corresponding controls. This colour change was associated with striking differences in microbial activity. In mid-December when the first estimate was made there were approximately 170 times as many bacteria per unit area on the treated compared with the non-treated leaves (Fig. 1). By early January the difference had fallen to times 48; thereafter it diminished progressively but residual effects of the urea treatment were still apparent in the spring.

In early March, all leaves were brought indoors to prevent the release of mature ascospores by rain, and their

Fig. 1. Capillary movement in hyphae of *Mucor mucedo*

## MICROBIOLOGY

Preparation of Fluorescent Polyvalent *Salmonella* antisera

IMMUNOFLUORESCENCE methods for detecting *Salmonellae* in meat<sup>1</sup> and egg products<sup>2</sup> have been described recently. In both investigations the indirect immunofluorescence technique<sup>3</sup> was used, involving treatment with rabbit polyvalent *Salmonella* agglutinating antisera, followed by staining with fluorescein conjugated goat anti-rabbit antiserum. This technique takes about two or three times as long as the direct technique using conjugated rabbit antisera originally described by Coons *et al.*<sup>4</sup>.

We therefore attempted to produce several fluorescent polyvalent *Salmonella* antisera, and to compare their staining characteristics with their agglutinating properties.

*Salmonella* O antigens were prepared by a process of heating and drying<sup>5</sup>. To obtain polyvalent antisera mixtures of equal weights of several antigens were injected into groups of rabbits. Each rabbit received nine 1-ml. intravenous injections at 3-4 day intervals, the first injection being equivalent to about 10<sup>6</sup> organisms and the last, 10<sup>10</sup> organisms. A week before the first injection small blood samples were obtained from each rabbit and checked for absence of agglutinins for the *Salmonellae* involved.

Three groups of rabbits were immunized in this way. The first group received O antigens 4; 7; 8; 9; 3, 10; 11; 3, 19; 13, 22, the second group received O antigens 4; 7; 8; 9 and the third group O antigens 3, 10; 11; 3, 19; 13, 22. Seven days after the last injections blood was drawn from each rabbit, held at room temperature for 5-7 h, and the serum collected. The sera from each group of rabbits (that is, those that received the same antigen mixture) were bulked. The O agglutination titres of the three bulked sera were determined against individual *Salmonellae* possessing the various antigens injected.

The  $\gamma$ -globulins of the three antisera were then precipitated by 50 per cent saturation with (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, centrifuged, and redissolved in phosphate buffered saline (pH 7.4). After dialysis against fresh buffered saline the globulins were conjugated with fluorescein isothiocyanate, the fluorochrome being added as a solid to the reaction

Fig. 1. Effect of 5 per cent urea on microbial activity in overwintering apple leaves

ascospore productivity determined by the method of Hutton and Burchill<sup>4</sup>. This consisted of taking random samples of 100 standard disks of leaf tissue from each treatment and agitating them in aerated water to discharge the ascospores from the perithecia. The resulting spore suspensions were concentrated by centrifugation and counted in a haemocytometer. The procedure was repeated on five successive occasions with each sample, with intervals to allow for further maturation of ascospores. The ascospore productivity was expressed as total ascospores liberated per cm<sup>2</sup> of leaf tissue (Table 1).

Table 1. EFFECTS OF UREA TREATMENTS ON THE ASCOSPORE PRODUCTIVITY OF APPLE LEAVES INFECTED WITH *Venturia inaequalis*

Treatment	Ascospore productivity total spores/cm <sup>2</sup> leaf	Percentage reduction
Sprayed M.III leaves		
Water	1,980	
2 per cent urea	906	55
5 per cent urea	57	97
Dipped M.III leaves		
Water	9,200	
5 per cent urea	280	97
Dipped 'Granny Smith' leaves		
Water	2,600	
5 per cent urea	84	97

Higher urea concentrations consistently reduced ascospore productivity by approximately 97 per cent compared with the water-treated controls. This was comparable with results obtained in other experiments with organo-mercurial fungicides. Although less marked, there was some inhibitory action by 2 per cent urea.

Decreased spore productivity seems to be due to the failure of the fungus to produce perithecia in the leaves, suggesting that inhibition may occur at an early stage in its development. Whether this is a direct effect of the increased nitrogen in the substrate or an indirect effect resulting from increased microbial activity is not yet known. Whatever the mode of action of urea, its use as a post-harvest spray suggests an alternative to organo-mercurial fungicides, and a possible approach to the control of apple scab by biological means.

mixture<sup>6,7</sup>. The globulin conjugates were freed of unconjugated dye by passing them through 'Sephadex G25', and concentrated to their original volumes by dialysis in polyethylene glycol (mol. wt., 20,000). The conjugated antisera were then tested for staining of *Salmonellae* from each of the *Salmonella* groups for which antigens had been prepared.

Tables 1 and 2 show the agglutination titres and staining characteristics of each of the three polyvalent antisera. Reasonable titres were obtained against each antigen, and in each case this corresponded with strong specific fluorescent staining of the relevant *Salmonellae*. For example, the polyvalent serum No. 1 stained all the organisms tested, but the polyvalent sera Nos. 2 and 3 stained only those organisms belonging to O groups for which the antisera showed agglutinating powers.

The conjugated polyvalent antisera described here are being assessed in routine immunofluorescence *Salmonella* tests on raw meat. Experience so far confirms that the direct technique may have worth-while advantages over the indirect technique used in our earlier investigations<sup>1</sup>. If necessary a series of such conjugated polyvalent antisera could be prepared, using group O antigens from all existing *Salmonella* groups.

### Colicin 15: Possibly a Defective Bacteriophage

COLICINS, bactericidal agents elaborated by many strains of the Enterobacteriaceae, have been classified as antibiotics<sup>1</sup>. Purified preparations of four colicins have been identified as lipocarbohydrate proteins<sup>2-5</sup>; a fifth apparently lacks the lipid component<sup>6</sup>. This communication presents evidence that an inducible colicin from *Escherichia coli*, WT15 (ref. 7), may be a defective bacteriophage.

*E. coli* WT15 produces colicin, with concomitant lysis of the cells, only after exposure to ultra-violet light or to certain chemicals. Azaserine is a convenient inducing agent for large quantities. Cells were grown in two portions of 2 l. each of glucose-ammonium salts medium<sup>8</sup> in 4-l. Erlenmeyer flasks on a rotary shaker at 37° C. When the concentration reached about 10<sup>8</sup> cells/ml., azaserine, in concentrated aqueous solution, was added until the final concentration was 0.4 µg/ml. While incubation, with shaking, continued, small samples were removed aseptically at intervals to determine their optical densities in the Coleman Universal Spectrophotometer at 540 mµ. When maximum lysis was achieved (about 4 h), the culture was saturated with (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> and stored at 5° C overnight. After refrigerated centrifugation at 3,900g for 30 min, the precipitate was resuspended in 73 ml. deionized H<sub>2</sub>O. During the next 48 h at a maintained temperature of 5° C the mixture was dialysed twice against 6 l. of deionized H<sub>2</sub>O with stirring. Insoluble debris was removed by centrifugation for 20 min at 14,350g. The supernatant fluid was chromatographed on diethylaminoethanol-

cellulose (DEAE) by a variation of the procedure of Goebel<sup>9</sup>. The sample (19 ml.), adjusted to pH 8.0 with 1 ml. M tris(hydroxymethyl)aminomethane, was added to the column (1.1 cm × 21 cm) of DEAE-cellulose, previously equilibrated to pH 8.0 with 0.05 M tris buffer. Gradient elution was achieved by the dropwise addition of 150 ml. of 0.3 M tris-0.5 M NaCl at pH 7.2 to a mixing chamber containing 150 ml. of 0.05 M tris at pH 8.0. Fractions of 1.5 ml. each were collected automatically at the rate of 0.1 ml./min and their optical densities determined at 280 mµ in a Beckman DU spectrophotometer. They were assayed for ability to inhibit the growth of a sensitive strain of bacteria. Uniform drops of two-fold serial dilutions of each fraction were placed on the surface of agar plates seeded with *E. coli* WT15. The plates were then incubated at 37° C for 18 h. The reciprocal of the greatest dilution producing a clearly defined zone of inhibition was arbitrarily assigned as the activity factor for the preparation. Results (Fig. 1A) indicate considerable purification of colicin, most of the biologically active material being eluted in Fractions 52-59. Before and after elution of the major part of the colicin some fractions showed relatively high absorption at 280 mµ, but little or no biological activity.

Fractions 52 through 59 (Fig. 1A) were combined and applied to a second column of DEAE-cellulose. Gradient elution was performed as previously described (Fig. 1B). Biological activity closely followed intensity of absorbance at 280 mµ, and single peaks of activity and absorbance were obtained. The fractions, negatively stained with phosphotungstic acid, were examined in the electron microscope. The quantity of bacteriophage-like bodies

Fig. 1. Colicin 15 chromatographed on DEAE-cellulose by gradient elution from 0.05 M tris buffer, pH 8.0, toward 0.3 M tris-0.5 M NaCl, pH 7.2. A, Fractionation of crude concentrate; B, second chromatogram of fractions 52 through 59 from A.

Fig. 2. An electron micrograph of purified colicin 15, negatively stained with phosphotungstic acid, showing empty heads, tails and apparently intact phage particles. The scale line represents 100 mμ. (x c. 59,300)

seemed to be correlated with the degree of biological activity of the preparation. Fraction 35, which exhibited a high degree of antibacterial activity, contained an abundance of phage elements (Fig. 2), consisting predominantly of empty heads but also showing tails and particles that appear to be intact phage. Fractions 30 and 51, which had little biological activity, contained few phage-like structures.

The identity of phage and colicin was confirmed by sedimentation of the pooled active fractions 35 and 36 (Fig. 1B) in high-density  $\text{NaNO}_3$  in deuterium oxide, density 1.28 g/ml. The sample (1.15 ml.), mixed with 3.15 ml. of the  $\text{NaNO}_3$  in  $\text{D}_2\text{O}$  to a density of 1.21 g/ml., was centrifuged in the SW 39 rotor (Spinco Model L ultracentrifuge) at 38,000 r.p.m. (159,000g) for 17 h. Five fractions (0.8 ml. each) were removed sequentially from top to bottom of the tube. Each was assayed microbiologically for colicin and examined in the electron microscope. Biological activity and phage were found only in the bottom fraction.

The particulate nature of this colicin was further evidenced by differential centrifugation and gel filtration. A concentrate of colicin (150 ml.), prepared by precipitation with  $(\text{NH}_4)_2\text{SO}_4$ , was thoroughly dialysed and centrifuged at 90,000g for 2 h. The lowest fifth of the total volume was removed and recentrifuged at 31,890g for 2 h. After the lower half of this preparation was dialysed overnight at 5° C against 0.1 M phosphate buffer at pH 7.0, 0.2 ml. was applied to a column of 4.3 ml. Sephadex G-200 in a 5-ml. serological pipette. The column was washed with 0.1 M phosphate buffer, pH 7.0. The excluded phase contained nearly all the biologically active material as well as an abundance of phage-like components. Since Sephadex G-200 has an approximate exclusion limit of a molecular weight of 200,000, colicin 15 apparently has a large molecular size.

Electron microscopic examination disclosed apparently intact phage particles in concentrates of colicin with high bactericidal activity against *E. coli* WT15. However, attempts to demonstrate typical lytic phage were unsuccessful. No plaques were produced by various preparations of colicin when tested in the usual manner against thirteen different strains of Enterobacteriaceae, including *E. coli* WT15.

Although colicins and temperate phages have long been thought to be related<sup>10</sup>, direct evidence has been lacking. In an electron microscope examination of colicinogenic strains, Kellenberger and Kellenberger<sup>11</sup> could not identify structural components that could be considered colicins. That colicins may represent the products of defective lysogeny has recently been suggested<sup>10,12</sup>. If so, colicins may range from relatively simple proteins to

completely formed phage particles. The identity of phage and colicin from *E. coli* WT15 suggests that bacterial lysis after induction may be a function of the development of the defective phage particle. Possibly smaller units, such as proteins, are secreted without lysis, whereas synthesis of discrete structures, such as heads or tails, results in cell disruption. These data strongly suggest that *E. coli* WT15 is a defective, lysogenic strain and that colicin 15 is a bactericidal component of its phage.

We thank Dr. Marion Barclay for assistance with the ultracentrifugation and Mr. Edgar Saunders for his help with the investigations in the electron microscope.

## ENTOMOLOGY

### Enforced Occurrence of a Mosaic Type Neurosecretory Cell in the Chrysomelid Beetle, *Galeruca tanacetii* (Linn.)

*Galeruca tanacetii* (Linn.) has a summer reproductive diapause followed by autumnal reproductive activities in the same year. A univoltine species, the adults of *Galeruca* emerge about the first week of June and remain in diapause until the middle of August when the ovarioles are completely undifferentiated. Development and maturation of the terminal oocytes are completed by mid-September, after which the females oviposit successive batches of eggs to the end of November. The interval between successive ovipositions varies between 7–10 days.

It has been found that photoperiod and temperature are the primary factors controlling diapause and reproduction. This beetle is a short-day species. The critical photoperiod is about 12 h/day at 20° C; at 15° C is probably about 2 h longer. With a 12 h photoperiod at 20° C, reproductive diapause is terminated in newly emerged females, which oviposit within 40 days. At photoperiods of 16 h and more, diapause is sustained and there is virtually no development of ovarioles within 70 days.

In the course of investigating the effect of transferring ovipositing and maturing females to a photoperiod of 16 h at 20° C, to examine the reproductive activities, two observations were made on the cytology of the neurosecretory cells of the pars intercerebralis of the brain. Ovipositing females laid an average of 1.8 batches of eggs per beetle and maturing females laid an average of 1.1 batches of eggs per beetle when transferred to these conditions in 30 days. They then reverted to

diapause within the experimental period. Post-mortem dissections revealed undeveloped eggs in the ovarioles.

Histological observations made on the neurosecretory cells of these experimental beetles using the alcian blue/phloxine technique<sup>1</sup> revealed that (a) the neurosecretory cells were comparable in cytology to those of diapause females, and (b) the A-cells contained within them phloxinophil granules. These mosaic type cells are comparable to the 'castration cells' of the suboesophageal ganglion of *Leucophaea maderae*<sup>2</sup> and in some hymenopterous species in which Thomsen<sup>3</sup> found both red and blue granules in the same cells using the chrome-haematoxylin/phloxine technique. I have used the alcian blue/phloxine and the chrome haematoxylin/phloxine techniques in cytological investigations of the neurosecretory cells and have not found any phloxinophil granules in the A-cells. In the control in this series of experiments, when maturing females were transferred to a photoperiod of 12 h at 20° C, they continued to lay eggs and their A-cells had no phloxinophil granules. It appears that the enforced occurrence of these mosaic type cells can be attributed to an altered metabolism of the beetle from a physiologically active reproductive phase to a non-active diapause phase as a result of changing its external environment.

## CYTOLOGY

### Labelled Cytoplasmic Organelles in *Allium cepa* Var. 'White Lisbon' after Administration of Tritiated Thymidine

THE specificity of tritium- or carbon-14-labelled thymidine as a precursor for deoxyribonucleic acid (DNA) appears to be good in many organisms<sup>1,2</sup>. Autoradiographs examined by light and electron microscopes have demonstrated that most of the label is incorporated into nuclear chromatin during the DNA synthetic phase of cell reproduction or during an exchange process in differentiated cells<sup>3-5</sup>. Occasional evidence for the cytoplasmic incorporation of thymidine has been obtained with animal cells after treatment with deoxyribonuclease<sup>6</sup>. In egg cells and developing embryos of vertebrates there is biochemical evidence for the presence of extranuclear DNA<sup>7-9</sup>.

In recent experiments, seedlings of *Allium cepa* were germinated on filter paper moistened with sterilized tap-water for 6-7 days at room temperature and then placed in tap-water containing 2.5 µc./ml. of tritiated thymidine (specific activity 2.7 c./mmole) for 1 h or 24 h. Root tips about 1-3 mm long were fixed in potassium permanganate<sup>10</sup> or osmium tetroxide<sup>11</sup> for 15 min-5 h, dehydrated in ethanol and embedded in 'Araldite'. Thin sections cut on a Porter-Blum MT2 ultramicrotome were transferred to 'Formvar' membranes<sup>12,13</sup> and coated with 'L4' emulsion (Ilford, Ltd.). Sections, 1-2 µ, placed on glass slides were coated with the same emulsion and the preparations were stored in light-proof boxes at approximately 4° C. 23-84 days later the autoradiographs were developed in 'D19b' (Kodak) for 2 min and fixed in 20 per cent sodium thiosulphate for 5 min at 20° C. The thin sections and superimposed autoradiographs were mounted on 3 mm copper grids<sup>12,13</sup> and examined either unstained or after heavy metal staining<sup>14,15</sup> in a Siemens Elmiskop I electron microscope. The autoradiographs of

Table 1. LIGHT MICROSCOPE AUTORADIOGRAPHS

		Labelled nucleus and cytoplasm	Labelled cytoplasm only	Labelled nucleus only	Unlabelled	
1 h	23 days	158	146	13	24	341
	51 days	148	130	9	34	321
	Per cent	46.3	41.7	3.3	8.7	100
24 h	23 days	399	19	—	2	420
	51 days	468	40	—	—	508
	Per cent	93.3	6.4	—	0.3	100

Table 2. ELECTRON MICROSCOPE AUTORADIOGRAPHS

Grain distribution over root tips fixed after 1 h in <sup>3</sup> H-thymidine							
Auto-radiograph exposure time	No. of cells	Grain distribution					Total grains
		Nucleus	Mito-chondria	Pro-plastids	Rest of cytoplasm	Cell wall	
23 days	15	461	18	31	15	4	529
	Per cent	87.1	3.4	5.9	2.8	0.8	100
84 days	15	743	61	52	23	16	895
	Per cent	83.0	6.8	5.8	2.6	1.8	100

thick sections were investigated using a phase contrast microscope. Control sections of unlabelled root tips were prepared in the same way.

Heavily labelled nuclei were observed in thick sections examined by light microscopy, together with some cytoplasmic labelling which in many cells was localized around the outside of the nuclear membrane or over groups of organelles distributed elsewhere in the cytoplasm. Nucleoli were not labelled in any of the preparations. The cytoplasmic labelling was observed over most meristematic cells and cells which were differentiating.

In sections of seedlings exposed to thymidine for 1 h before fixation, 46.3 per cent of the cells had labelled nuclei and cytoplasm and 41.7 per cent had labelled cytoplasm only. A smaller proportion of cells were unlabelled (Table 1). After 24 h nearly all the meristematic cells and differentiating cells had labelled nuclei and cytoplasm. The cells with labelled cytoplasm only were mainly, but not exclusively, situated in the boundary zone between root cap and meristem at 24 h.

Fig. 1. Electron microscope autoradiograph of a root tip meristem cell exposed to tritiated thymidine for 1 h. Developed photographic grains occur over nuclear chromatin. ( $\times 18,000$ )

Fig. 2. Electron microscope autoradiograph of root tip exposed to thymidine for 1 h. Developed photographic grains are visible over the internal matrix of proplastids. ( $\times 30,000$ )

Electron microscope autoradiographs showed the same distribution of developed silver grains over nuclei and cytoplasm as the light microscope preparations, with most grains occurring over nuclear chromatin (Fig. 1 and Table 2). Over the cytoplasm, developed grains were seen over mitochondria, and also over structures termed 'proplastids'<sup>16</sup>, but which could be immature mitochondria<sup>17</sup>, in considerably greater numbers than over the remaining cytoplasm and cell walls (Table 2). The grains were more frequently observed over the internal matrix and membranes of the mitochondria and proplastids than over the boundary membranes (Fig. 2). In many cases grains were associated with fibres similar in appearance to those shown by Nass and Nass<sup>20,21</sup> to be removed by deoxyribonuclease.

These results are interesting in view of recent electron cytochemical evidence<sup>18-21</sup> supporting earlier suggestions<sup>6,22</sup> that mitochondria and plastids may contain DNA.

The high concentration of grains over nuclear chromatin and, to a lesser extent, over proplastids and mitochondria, taken in conjunction with the lack of grains over nucleoli and ribosomes, suggest that in our autoradiographs the thymidine has been incorporated into DNA and not into ribonucleic acid (RNA). Enzymatic experiments using nucleases are in progress.

The results included in Table 1 indicate that during the first hour of thymidine administration label is incorporated into the mitochondria and proplastids of some cells which are not in the nuclear DNA synthetic phase. In view of the high proportion of cells with labelled cytoplasm only at this time (Table 1) it seems likely that mitochondria and proplastids are labelled independently from nuclei which are in the DNA synthetic phase, and they probably do not become labelled by passage of already labelled DNA out of the nucleus. It is possible that mitochondrial and proplastid DNA synthesis is required for the production of new organelles in the cytoplasm<sup>23</sup> or as a stage in the addition of material to

nuclear DNA<sup>6</sup>. Further experiments which are in progress should throw more light on these possibilities.

### A Cytoplasmic Organelle of Melanocytes

DURING his classical investigations of intracellular organelles Claude isolated melanin granules from the liver of *Amphiuma tridactylum*<sup>1</sup>. Sections of these granules were later examined by Drochmans, who showed them to possess definite structural detail<sup>2</sup>. Other investigations have shown the existence of a highly regular, almost crystalline lattice in melanin granules from other tissues<sup>3</sup>. Melanin itself was suggested by Longuet-Higgins as having properties of a one-dimensional semi-conductor<sup>4</sup>, and this was agreed on by Pullman<sup>5</sup>. Semiquinone free radicals have been demonstrated in melanin granules and the characteristic signals<sup>6</sup> became more pronounced during irradiation of such granules with light<sup>7,8</sup>.

Evidence such as that summarized here suggested that melanin granules might play some part in the energy metabolism of the cells in which they abound<sup>9,10</sup>. This seemed to be particularly pertinent to the pigment cells of the human nervous system since depigmentation of these cells is a frequent finding in some extra-pyramidal diseases<sup>11,12</sup>.

Electron microscopic investigations of osmium-fixed *Amphiuma* liver showed that the hepatocytes contained large numbers of mitochondria. In contrast to these cells, the melanocytes contained either few or no mitochondria. Instead, the dominant cytoplasmic organelles of the melanocytes were uniform round bodies measuring approximately  $2.2\mu$  in diameter. Each of these was bounded by a membrane which, in some of the micrographs, appeared to be double. This membrane enclosed several dense melanin granules as well as many concentrically laminated sub-units. While the melanin granules were of the same uniformity as that demonstrated by Claude<sup>1</sup>, the concentrically laminated sub-units varied in size, in shape and in density. However, they were always less dense than the melanin granules and were always oval or round.

Examination of formalin-fixed paraffin sections stained with hæmatoxylin and eosin showed different degrees of pigmentation of the granules from one cell to the next, but apparent uniformity of pigmentation within each cell. The granules were clearly visible and were seen to occur

Fig. 1. The large electron-micrograph shows a thin section of an osmium-fixed, uranyl-acetate-stained intracellular organelle like those described in the text ( $\times c. 33,200$ ). The inset is a photomicrograph of an entire organelle, from a homogenate in 0.25 M sucrose stained with toluidine blue. Two melanin granules attached to each other are seen outside this organelle ( $\times c. 3,600$ ).

mostly in clumps. As opposed to the melanin granules, the larger body in which the granules were embedded could not be seen. After incubation of de-paraffinized sections in 30 per cent hydrogen peroxide for 24 h at room temperature the melanin granules could no longer be seen but the cytoplasm was now studded with vacuoles. These were larger than the melanin granules but it was difficult to measure their size because their boundaries were not clear. Furthermore, the cytoplasm of the melanocytes was ash coloured and showed a foamy appearance. Neither the cytoplasm of the hepatocytes nor the nuclei of all the cells investigated had changed their appearance following incubation with hydrogen peroxide. In addition, the cell membranes of the melanocytes were much more prominent after this incubation than they had been before. It was therefore improbable that the vacuolated appearance of only the cytoplasm of the melanocytes was due to an artefact. On the contrary, in view of the earlier description of phagocytic 'vacuoles'<sup>13</sup> in melanophages<sup>14</sup> this finding could have indicated that the intracellular organelle under examination was merely a vacuole.

A critical experiment was thought to be one in which the integrity of these bodies could be demonstrated following the rupture of the cell membrane. It was assumed that these bodies must be fragile otherwise they would have been isolated earlier. Therefore, liver suspensions in 0.25 M sucrose were made gently, namely, by a single passage through a tissue press followed by a single excursion of a slowly rotating 'Teflon' pestle through a Potter-Elvehjem homogenizer. Such suspensions showed an abundance of the bodies we were seeking among unbroken cells, cellular debris and free melanin granules. The bodies were round in shape and contained one or more melanin granules embedded in a pale refractive matrix. However, these bodies were not so uniform as we had expected them

to be from the electron micrographic examinations. Indeed, some were seen to swell during prolonged observation of suspensions in sucrose solution. These organelles were not observed to take up free melanin granules. The latter often adhered to each other in strands or in clumps. The matrix of the large organelles was readily stained by toluidine blue and more slowly by janus green B.

It was pertinent to ask whether this intracellular organelle was peculiar to the *Amphiuma* liver. Preliminary observations were therefore made on an osmium-fixed sample of *Substantia nigra* obtained from a human autopsy 2 h after death (BNL Hospital No. A-201-64). Electron microscopic investigation revealed the presence of many cytoplasmic bodies containing primarily dense melanin granules. These bodies were round or polygonal, about one-third the size of those seen in *Amphiuma* liver, and were arranged in clusters within the cytoplasm. Neither the boundaries of these bodies nor their fine structure could be examined accurately because autolysis had already set in. However, the resemblance between these bodies and those described in *Amphiuma* liver was close enough to make it likely that they are the same type of organelle.

It is of interest that arrangements of melanin granules bearing some similarities to those shown by our electron microscopic investigations have been encountered by earlier workers in a variety of tissues. These have been variably designated as phagocytic vacuoles<sup>15</sup>, as conglomerate granules<sup>16</sup>, as melanin-building centres<sup>17</sup>, as melanin spherules<sup>18</sup>, as irregular inclusions<sup>19</sup>, or as compound granules<sup>20</sup>. We would expect that some of these might maintain their structural integrity after completion of the homogenization necessary for their isolation in bulk.

The demonstration of this discrete integrated intracellular organelle indicates that the metabolism of melanins is a much more complex process than we thought it to be during the initial phases of this work<sup>11,12</sup>.

This work was supported by the U.S. Atomic Energy Commission.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, February 1

SOCIETY OF ENGINEERS (in the Apartments of the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Inaugural Meeting for the year 1965. Mr. C. L. N. Laing: Presidential Address.

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Members' Discussion on "The Society's Publications". Discussion Leader: Prof. W. G. Overend.

INSTITUT FRANCAIS DU ROYAUME-UNI (at Queensberry Place, South Kensington, London, S.W.7), at 8.15 p.m.—French Scientific Films.

## Tuesday, February 2

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. K. Wolfe: "The Refurbishing of Engineers in the U.S.A."

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Dr. K. McCarthy: "Studies with Rubella Virus". (Sixth of sixteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)\*

PLASTICS INSTITUTE, LONDON SECTION (at the Wellcome Building, Euston Road, London, N.W.1), at 6.30 p.m.—Mr. A. L. Ashton and Mr. J. E. H. Hayward: "Newer Thermosetting Materials".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the University College Chemical and Physical Society, at University College, Gower Street, London, W.C.1), at 6.30 p.m.—Prof. A. J. Birch, F.R.S.: "Some New Synthetic Reactions Applied to Steroids".

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 7.15 p.m.—Dr. Harold E. Edgerton: "Electronic Flash Photography".

## Wednesday, February 3

ROYAL MICROSCOPICAL SOCIETY, and the BRITISH MICROCIRCULATION SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), from 11 a.m. to 7 p.m.—Symposium on "Living Microscopy".

COLOUR GROUP (Great Britain) (in the Physics Department, Imperial College, Prince Consort Road, London, S.W.7), at 2 p.m.—Meeting on "Methods of Assessing Colour Rendering". Speakers: Dr. J. L. Ouweltjes, Dr. B. H. Crawford and Dr. D. A. Palmer.

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 2 p.m.—Dr. D. Penington: "Regulation of Bone Marrow Activity".\*

SOCIETY FOR ANALYTICAL CHEMISTRY, SPECIAL TECHNIQUES GROUP (joint meeting with the Spectroscopy Group of the Institute of Physics and the Physical Society, at the Wellcome Building, Euston Road, London, N.W.1), at 3 p.m.—Meeting on "New Light Sources in Spectroscopy".

GEOLOGICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. G. P. Butler, Mr. C. G. St. C. Kendall, Dr. D. J. J. Kinsman, Mr. D. J. Shearman and Sir Patrick A. d'E. Skipworth, Bt.: "Recent Anhydrite from the Trucial Coast of the Arabian Gulf".

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5 p.m.—Dr. M. B. Priestley: "Evolutionary Spectra and Non-Stationary Processes".

ROYAL SOCIETY OF MEDICINE, HISTORY OF MEDICINE SECTION (at 1 Wimpole Street, London, W.1), at 5.15 p.m.—Dr. Edwin Clarke: "Nicolas Stensen and the Brain".

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. C. R. Major and Mr. A. C. Moore: "The Economics of Motor Gasoline Quality".

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. D. J. Bolton: "A Seasonal Tariff for Domestic Supplies".

UNIVERSITY OF LONDON (in the Botany Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. J. C. Kendrew: "The Genetic Determination of Protein Function".\*

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, JOINT I.E.R.E./I.E.E. Medical Electronics Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Discussion on "Safety of Operating Theatre Equipment".

INSTITUTION OF MECHANICAL ENGINEERS, PROCESS ENGINEERING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion Meeting on "Data Recovery".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2) at 6 p.m.—Mr. Cecil J. Allen: "The Future of Railways".

SOCIETY OF ENVIRONMENTAL ENGINEERS, PACKAGING GROUP (in the Mechanical Engineering Department, Imperial College of Science and Technology, London, S.W.7), at 6 p.m.—Mr. D. B. Osborn: "Cushion Design".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the Chelsea College Chemical Society, at Chelsea College of Science and Technology, Manresa Road, London, S.W.3), at 7 p.m.—Sir Cyril Hinshelwood, O.M., F.R.S.: "The Evolution of Kinetics".

## Thursday, February 4

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. R. H. Kay: "Bioluminescence of a Planktonic Crustacean"; Mr. B. E. B. Moseley and Mr. H. Laser: "Repair of Ionizing Radiation Damage in Radiation Resistant Bacteria".

ROYAL INSTITUTION, LIBRARY CIRCLE (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Mr. Gordon Ratray Taylor: "Biological and Botanical Books Old and New".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. J. W. B. Douglas: "Health and School Achievement". (Seventh of sixteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)\*

CHEMICAL SOCIETY (in the Physics Lecture Theatre, Imperial College of Science and Technology, South Kensington, London, S.W.7), at 6 p.m.—Prof. F. Sondheimer: "Syntheses in the Cardiac-Active Steroid Field". (Tilden Lecture.)

INSTITUTE OF REFRIGERATION (at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, Southwark Bridge Road, London, S.E.1), at 6 p.m.—Dr. A. J. Barnard: "Refrigeration Plant for the Quick-Freezing Industry".

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS (at 9 Bedford Square, London, W.C.1), at 6 p.m.—Major-General B. D. Kapur: "Development of Electronics in India".

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMATIC CONTROL GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion Meeting on "Synthesizing Hydraulic Control Systems from Available Components".

ROYAL AERONAUTICAL SOCIETY (at 4 Hamilton Place, London, W.1), at 6 p.m.—Prof. J. H. Argyris: "Current Work in the Structures Field".

## Friday, February 5

TELEVISION SOCIETY (in the I.T.A. Conference Suite, 70 Brompton Road, London, S.W.3), at 7.45 p.m.—Dr. N. Mayer (Munich): "The N.T.S.C. Colour Television System Using Additional Reference Transmission".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. D. M. MacKay: "The Eye and the Brain".

## Monday, February 8

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 4 p.m.—Dr. B. Ackner: "Organic Mental Syndromes".\*

BRITISH SOCIETY FOR THE PHILOSOPHY OF SCIENCE (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. H. Bondi, F.R.S.: "The Disproof of Theories".

UNIVERSITY OF LONDON (in the Physiology Department Theatre, St. Bartholomew's Hospital Medical College, West Smithfield, London, E.C.1), at 5.30 p.m.—Prof. K. J. Ullrich: "Characteristics of Renal NaCl-transport, and Its Modification by Aldosterone and Saluretic Sulphonamides".\*

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, W.C.2), at 6.30 p.m.—Mr. B. W. Leyland: "Earth Return Applied to High Voltage Systems".

ROYAL AERONAUTICAL SOCIETY, HISTORICAL GROUP (at 4 Hamilton Place, London, W.1), at 7 p.m.—Sqn./Ldr. S. C. Winfield Smith: "British Aviation Fifty Years Ago".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. J. B. Ward Perkins, C.B.E.: "The Changing Historical Landscape of Italy".

## Monday, February 8—Tuesday, February 9

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2)—Conference on "Electronics Design".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

PRINCIPAL LECTURER (with high academic qualifications, and preferably industrial or research experience) IN MATHEMATICS—The Registrar, Lancaster College of Technology, Priory Street, Coventry (February 2).

ASSISTANT LECTURERS OR LECTURERS (2) IN THE DEPARTMENT OF MATHEMATICS—The Registrar, University of York, Heslington, York (February 12).

ASSISTANT LECTURER (preferably with special interests in fungi) IN THE DEPARTMENT OF BOTANY; an ASSISTANT LECTURER IN ORGANIC CHEMISTRY and an ASSISTANT LECTURER IN INORGANIC CHEMISTRY; an ASSISTANT LECTURER IN GEOLOGY; a LECTURER/ASSISTANT LECTURER IN THE HISTORY AND PHILOSOPHY OF SCIENCE; ASSISTANT LECTURERS (2) IN THE DEPARTMENT OF PHYSICS; an ASSISTANT LECTURER IN THE DEPARTMENT OF PSYCHOLOGY; an ASSISTANT LECTURER IN THE DEPARTMENT OF ZOOLOGY; and an ASSISTANT LECTURER IN BIOLOGY—The Secretary, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devonshire (February 11).

LECTURER IN NUMERICAL ANALYSIS, and an ASSISTANT LECTURER IN MATHEMATICAL STATISTICS—The Registrar, The University, Leicester (February 13).

LECTURER IN THE DEPARTMENT OF PSYCHOLOGY; and LECTURERS (2) IN THE DEPARTMENT OF SOCIOLOGY—The Registrar, The University, Leicester (February 13).

ASSISTANT LECTURER (preferably with an interest in developmental research) IN PSYCHOLOGY—The Registrar, The University, Sheffield (February 15).

LECTURER (preferably with a special interest in the nutritional aspects of biochemistry) IN BIOCHEMISTRY—The Secretary of the University Court, The University, Glasgow (February 15).

SENIOR LECTURER and a LECTURER (specialists in one or more of the following fields: econometric theories, applied econometrics, mathematical programming, input-output analysis, sources of economic statistics) IN THE DEPARTMENT OF ECONOMETRICS—The Registrar, The University, Manchester, 13 (February 17).

EXPERIMENTAL OFFICER (with some experience in organic microanalysis) for microanalysis IN THE DEPARTMENT OF CHEMISTRY—The Registrar, The University, Manchester, 13 (February 19).

LECTURER (with an honours degree and experience of control engineering and/or electrical machines) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING—The Registrar, The University, Leeds, 2 (February 22).

**PROFESSOR AND HEAD** (with a higher degree, preferably a doctorate, research experience in the field of plant science, and preferably experience in university teaching) of the Department of Botany, University of Queensland, Australia—Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, February 26).

**TURNER AND NEWALL RESEARCH FELLOWS IN ENGINEERING, INORGANIC CHEMISTRY, PHYSICS** and allied subjects—The Registrar, The University, Manchester, 13 (February 27).

**ASSISTANT LECTURER IN THE DEPARTMENT OF APPLIED MATHEMATICS**—The Registrar, University College of Wales, Aberystwyth (February 28).

**CHAIR OF BIOLOGICAL SCIENCE** at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (February 28).

**LECTURER AND AN ASSISTANT LECTURER IN THE DEPARTMENT OF BIOCHEMISTRY**—The Secretary, University College, Gower Street, London, W.C.1 (March 1).

**READER IN ANTHROPOLOGY**—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (March 1).

**READER IN ELECTRICAL ENGINEERING SCIENCE IN THE NEW DEPARTMENT OF ENGINEERING SCIENCE**—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (March 1).

**SENIOR LECTURER AND A LECTURER IN THE DEPARTMENT OF STATISTICS**—The Secretary, The University, Aberdeen, Scotland (March 1).

**CHAIR OF VETERINARY ANATOMY OR VETERINARY PHYSIOLOGY** at the University of Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (March 2).

**LECTURERS** (preferably with special qualifications and experience in cell physiology, plant biochemistry, experimental taxonomy, cytogenetics or microbiology) in **BOTANY** at the University of Ghana—The Assistant Registrar, University of Ghana Overseas Office, 15 Gordon Square, London, W.C.1, or The Registrar, University of Ghana, P.O. Box 25, Legon, Accra, Ghana (March 3).

**POST-DOCTORAL RESEARCH ASSISTANTS IN ORGANIC CHEMISTRY** for synthetic work related to cephalosporin C and the penicillins—Dr. G. Lowe, The Dyson Perrins Laboratory, The University, South Parks Road, Oxford (March 6).

**LECTURER OR ASSISTANT LECTURER IN SOCIAL ANTHROPOLOGY** in the School of African and Asian Studies—The Assistant Registrar (Establishment), University of Sussex, Stanmer House, Stanmer, Brighton, Sussex (March 10).

**LECTURER OR ASSISTANT LECTURER** (with special interests in economic geology) in the **DEPARTMENT OF GEOLOGY**—The Registrar, University College of Swansea, Singleton Park, Swansea (March 20).

**DEMONSTRATOR** (preferably with postgraduate research experience and a special interest in fungal genetics or cytology) in the **DEPARTMENT OF AGRICULTURAL BOTANY**—The Registrar, University College of Wales, Aberystwyth (March 31).

**POST-DOCTORAL FELLOW** to work on new methods of peptide synthesis in collaboration with Dr. C. J. M. Stirling—Prof. H. B. Henbest, Department of Chemistry, Queen's University, Belfast, Northern Ireland (March 31).

**PROFESSOR AND HEAD OF THE DEPARTMENT OF FORESTRY**—The Secretary and Registrar, The University College of North Wales, Bangor, North Wales (March 31).

**ASSISTANT LECTURER OR LECTURER IN ORGANIC CHEMISTRY**—The Registrar, University College of Swansea, Singleton Park, Swansea (April 5).

**CHAIR OF PHYSICAL CHEMISTRY**—The Registrar, University College of Swansea, Singleton Park, Swansea (May 1).

**ASSISTANT LECTURER (Demonstrator) IN THE DEPARTMENT OF ANATOMY** (Prof. J. Z. Young, F.R.S.) to undertake teaching and research—The Secretary, University College, Gower Street, London, W.C.1.

**ASSISTANT MASTER** to teach Mathematics to scholarship level—The Headmaster, Merchant Taylors' School, Sandy Lodge, Northwood, Middlesex.

**D.S.I.R. RESEARCH ASSISTANT** (with some experience of electro-physiological techniques) in the **ZOOLOGY DEPARTMENT**, to work with Dr. E. J. Binyon on the neuromuscular physiology of certain echinoderms—The Professor of Zoology, Royal Holloway College (University of London), Englefield Green, Surrey.

**RESEARCH ASSISTANT** (preferably with chemistry, physics or biochemistry qualifications) for a M.R.C. project on ion transport across living membranes—Prof. H. E. de Wardener, Department of Medicine, Charing Cross Hospital Medical School, Fulham Hospital, London, W.6.

**RESEARCH FELLOW** (graduate in electrical engineering, physics or mathematics) in the **DEPARTMENT OF ELECTRICAL ENGINEERING**, for studies in the synthesis of lumped linear electrical networks—The Registrar, The University, Leicester.

**SENIOR LECTURER OR READER** (academically well qualified and with lecturing as well as significant research and/or industrial experience) in the **DEPARTMENT OF INDUSTRIAL CHEMISTRY**—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref. 1/G.

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

### Great Britain and Ireland

The Gas Council. Research Communications. GC105: The Gas Council Basic Research Group—Its Aims and Objectives. By Dr. J. A. Gray. Pp. 8. GC104: Report on the Gas Council Research Scholarships, 1964. Pp. 4. GC106: The Catalytic Gasification of Petroleum Feedstocks. By Dr. R. G. Cockerham and T. A. Yarwood. Pp. 15. GC107: Recent Field and Laboratory Investigations Into Domestic Warm Air Heating. By E. W. G. Dance, J. A. Harris and D. R. Wills. Pp. 34. GC108: Forced-Convection Techniques for Gas-Fired Rapid Billet Heating. By M. N. Lawrence and J. Spittle. Pp. 16. GC109: The Design and Control of a Range of Self-Propportioning, Nozzle-Mixing, Tunnel Burners. By M. L. Hoggarth and P. F. Aris. Pp. 24. GC110: Air/Gas Proportioning Techniques for Industrial Burners. By R. A. Hancock. Pp. 16. GC111: 55th Report of the Joint Refractories Research Committee, 1963-64. Pp. 27. GC112: Further Experiments with a Slagging Pressure Gasifier. By Dr. D. Hedden, Dr. J. A. Lacey and A. G. Horsler. Pp. 16. GC113: The Gasification of Coal in an Experimental Rummel Double-Shaft Slag-Bath Gasifier. By Dr. M. MacCormack and J. Wrobel. Pp. 14. GC114: Applications of Modern Analytical Techniques in the Gas Industry. Part 2: The Complete Analysis of Fuel Gases by Gas Chromatography. By Prof. A. L. Roberts and Dr. C. P. Ward. Pp. 10. GC115: Domestic Aerated Burners for Methane. By J. A. Harris and J. A. Prigg. Pp. 19. GC116: The Use of New Analytical

Techniques in Control and Research. By G. R. Boreham and W. E. Armstrong. Pp. 22. (London: The Gas Council, 1964.) [2511]

Building Research Station Digest (Second Series), No. 52: Space and Water Heating in Local Authority Flats. Pp. 4. (London: H.M. Stationery Office, 1964.) 4d. [2511]

General Register Office. Census 1961: England and Wales. Housing National Summary Tables. Pp. v+14. (London: H.M. Stationery Office, 1964.) 2s. 6d. net. [2511]

Ciba (A.R.L.), Ltd. Technical Notes, No. 262 (October 1964): Church Furniture Bonded with Aerolite. Pp. 8. (Duxford: Ciba (A.R.L.), Ltd., 1964.) [2511]

### Other Countries

Institut für Atomenergie, Kjeller Research Establishment. Kjeller Report No. 79: Quarterly Progress Report, April-May-June, 1964. Pp. iv+25. (Kjeller: Institut für Atomenergie, Kjeller Research Establishment, 1964.) [2511]

Population Reference Bureau, Inc. Population Bulletin, Vol. 20, No. 6 (October, 1964): United Nations: Population Opinion Survey. Pp. 141-172. (Washington, D.C.: Population Reference Bureau, Inc., 1964.) 50 cents. [2511]

Transactions of the American Philosophical Society. New Series, Vol. 54, Part 6: John Daly Burk—Irish Revolutionist and American Patriot. By Joseph I. Shulim. Pp. 60. (Philadelphia: The American Philosophical Society, 1964.) 2 dollars. [2511]

The National Parks of Queensland, Australia. Pp. 32. (Brisbane: State Public Relations Bureau, Premier's Department, 1964.) [2511]

Proceedings of the United States National Museum, Smithsonian Institution. No. 3475, Vol. 114: Moths of the Family Acrolophidae in America North of Mexico (Microlepidoptera). By Frank F. Hasbrouck. Pp. 487-706. No. 3494, Vol. 116: A Review of the Ophioid Fish Genus *Oligopus* with the Description of a New Species from West Africa. By Daniel M. Cohen. Pp. 1-22+5 plates. No. 3496, Vol. 116: A Survey of Vertebral Numbers in Sharks. By Victor G. Springer and J. A. F. Garrick. Pp. 73-96+1 plate. No. 3498, Vol. 116: One New Species and Two Redescriptions of Catfishes of the South American Cichlid Genus *Corydoras*. By Stanley H. Weitzman. Pp. 115-126. No. 3499, Vol. 116: Osteology and Relationships of South American Characid Fishes of Subfamilies Lebiasinidae and Erythrinidae with special reference to Subtribe Nannostomina. By Stanley H. Weitzman. Pp. 127-170. (Washington, D.C.: Government Printing Office, 1964.) [2511]

Arctic Institute of North America. Technical Paper No. 15: The Lemming Cycle at Baker Lake, Northwest Territories, During 1959-62. By Charles Krebs. Pp. 104. (Montreal, Washington, D.C., and New York: Arctic Institute of North America, 1964.) 2 dollars. [2511]

World Meteorological Organization. Technical Notes. No. 53: The Effect of Weather and Climate Upon the Keeping Quality of Fruit. By G. C. Green. Pp. xxi+180. (WMO-No. 137. TP.63.) 8 Sw. francs. No. 55: The Influence of Weather Conditions on the Occurrence of Apple Scab. (Report of a working group of the Commission for Agricultural Meteorology, prepared by J. J. Post, C. C. Allison, H. Burckhardt and T. F. Preece.) Pp. xi+41. (WMO-No. 140. TP.65.) 5 Sw. francs. No. 56: A Study of Agroclimatology in Semi-Arid and Arid Zones of the Near East. By G. Perrin de Brichambaut and C. C. Wallén. Pp. xv+64. (WMO-No. 141. TP. 66.) 6 Sw. francs. No. 59: Windbreaks and Shelterbelts. (Report of a working group of the Commission for Agricultural Meteorology, prepared by J. van Eimera, R. Karschun, L. A. Razumova and G. W. Robertson.) Pp. xv+188. (WMO-No. 147. TP.70.) 10 Sw. francs. No. 60: Meteorological Soundings in the Upper Atmosphere. By W. W. Kellogg. Pp. vii+46. (WMO-No. 153. TP. 73.) 8 sw. francs. (Geneva: World Meteorological Organization, 1963 and 1964.) [2511]

National Academy of Sciences—National Research Council. Ground-Based Astronomy: a Ten-Year Program. (A Report prepared by the Panel on Astronomical Facilities from the Committee on Science and Public Policy of the National Academy of Sciences.) Pp. 105. (Washington, D.C.: National Academy of Sciences—National Research Council, 1964.) [2511]

Nuclear Structural Engineering, Vol. 1, No. 1 (January, 1964). Edited by Thomas A. Jaeger. Pp. 1-140. Published bi-monthly. Subscription price per volume of 500 pages, 90 D.fl.; 180s.; 25 dollars. (Amsterdam: North-Holland Publishing Company, 1964.) [2511]

World Health Organization. Protection Against Ionizing Radiations: a Survey of Existing Legislation. (Offprint from Vol. 15, No. 2 of the *International Digest of Health Legislation*.) Pp. 170. (Geneva: World Health Organization; London: H.M. Stationery Office, 1964.) 6 Sw. francs; 10s.; 2 dollars. [2511]

European Atomic Energy Community—Euratom. Euratom's Biology Programme 1961-1964—Report and Perspectives. By R. K. Appleyard. Pp. 37. (Eur. 1884.e.) (Brussels: European Atomic Energy Community—Euratom, 1964.) [2511]

Instituto Antártico Argentino. Publicación No. 10: Nomenclatura del Hielo en el Mar. Por Rodolfo N. Panzarini. Pp. 103. (Buenos Aires: Instituto Antártico Argentino, 1963.) [2511]

Report and Accounts of the National Botanic Gardens of South Africa (Kirstenbosch, Newlands, Cape; Karoo Garden, Worcester; and Harold Porter Botanic Reserve, Betty's Bay), for the financial year ended 31 March 1964. Pp. 56. (Kirstenbosch, Newlands, C.P.: National Botanic Gardens of South Africa, 1964.) [2511]

The Journal Literature of Physics: a Comprehensive Study Based on *Physics Abstracts* (Science Abstracts) (Section A), 1961 Issues. By Stella Keenan and Pauline Atherton. Pp. 156. (New York: The American Institute of Physics, 1964.) [2511]

# UNICAM SP.800

spectrophotometer for routine  
U.V. analysis and complete  
**automation**

The brilliant new Unicam SP.800 Spectrophotometer is setting new standards in ultraviolet and visible Spectroscopy. The widely acclaimed flat bed presentation, the beam balance smoothing cam and the unique second sample position are among the features which establish it as *the* outstanding U.V. spectrophotometer. Now, in addition, Unicam offer a set of automation accessories which provide facilities for:

**AUTOMATIC** interchange of up to 4 sample and 4 reference cells

**AUTOMATIC** re-cycling over any preselected wavelength range

**AUTOMATIC** recordings at predetermined time intervals.

*Please send for descriptive brochure*

*Save operator time, increase speed and efficiency with Unicam automation for:*

ENZYME REACTION RATES

LIQUID COLUMN CHROMATOGRAPHY

ALL ROUTINE ULTRAVIOLET AND  
VISIBLE SPECTROSCOPY

# vibration TESTING

All things that move continuously are subject to vibration—machines, buildings, vehicles, aircraft, etc. This hidden force can affect the length of life and even the safety of all structures and components. It is therefore vital to know precisely the degree of vibration that is likely to occur, at what stage and with what effect. To-day the technology of Vibration Testing is an exacting science and the advanced techniques of DEV Test Systems place them in the forefront of this field.

## MINISTERS OF THE CROWN ACT, 1964

THE Machinery of Government Bill\*, which received an unopposed second reading in the House of Commons on November 19, provides the usual structure for the new Departments of State. These are the Ministry of Land and Natural Resources, the Ministry of Overseas Development and the Ministry of Technology. The Bill also amends the statutory restrictions on the number of Ministers who may sit in the House of Commons. The Attorney-General, in moving the second reading, described it as a purely technical Bill, but his assertion that it involved no questions of constitutional principle was challenged. It provides a limit of 91 in place of the 70 prescribed by the House of Commons Disqualifications Act of 1957 for Ministers who may sit in the House of Commons. While it is concerned with the establishment of new Ministries, it does not deal with their functions: these are to be dealt with by subsequent measures. (During the debate that followed, the Chancellor of the Duchy of Lancaster assured the House that there would be opportunity to debate these functions at a later stage.) The Attorney-General explained the reason for the several clauses, including the abolition of the limit of 27 on the number of Ministers holding senior offices who may sit and vote in the House of Commons.

Mr. Selwyn Lloyd, who followed, nevertheless asked for information regarding the function of the new Ministries and pointed out the constitutional issue which the Attorney-General had evaded. Quoting the report of the Herbert Committee in 1941, he reminded the House that that Committee had laid down as a principle the need to limit the control or influence of the executive Government over the House of Commons by means of an undue proportion of office holders being members of the House. He thought that the present figure of 91 was a clear breach of the principle laid down by that Select Committee, which did not contemplate one higher than 60 and took a serious view of the possible effect on the constitutional development of the House of a considerable increase in, for example, the number of Parliamentary Private Secretaries. Sir Derek Walker-Smith also insisted that for such reasons the Bill went to the very heart of the function of Parliament, the genesis of which lay in seeking to exercise control over the Executive.

Mr. J. Grimond considered that the House of Commons had far too few opportunities for discussing the machinery of Government, and thought that it was time that the changes that had occurred piecemeal for some time were fully examined, including the recasting of the Ministry of Defence by the previous Government. He complained that the Attorney-General had not met the need, and quoted the view of the Haldane Committee that any improvement in the organization of the Departments of State which was so marked as to increase substantially their efficiency should have as its correlative an increase in the power of the Legislature as the check on the acts and proposals of the Executive. Further, the duties of a member of Parliament were changing, and unless he

accepted the new role, his influence would continue to diminish. It was essential to find methods of being better informed, and Mr. Grimond thought that the first function of the debate was to obtain as much information as possible from the Government about the new Ministries and the need for their formation. He was sceptical of the proliferation of Ministries as well as about the absolute increase in the number of Ministers who could sit and vote in the House of Commons.

Sir Kenneth Pickthorn, who had been a member of the Herbert Committee, also emphasized the constitutional issue, and Mr. J. Percival questioned whether the object in increasing the number of Ministers allowed to sit in the House of Commons was to increase the control of the Executive over Parliament. Mr. W. R. van Straubenzee insisted that the first requirement was that Ministers should be responsible to the House of Commons, and he was particularly concerned over the increase in the number of paid Government Whips. He thought that the general public were also uneasy at the greater hold of the party machine on the average back-bencher. The constitutional issues were also recognized by Mr. A. Buck, Mr. E. M. Taylor and some others, while Mr. R. A. Butler put as the first issue the undesirable increase in the Executive in relation to the Legislature, supporting Mr. Grimond's plea for further enquiry, for example, by a Select Committee following up the Haldane Report.

Replying for the Government, the Chancellor of the Duchy of Lancaster, Mr. D. Houghton, admitted that some aspects of the machinery of Government and of the structure and functions of departmental organization might require more consideration. He brushed aside constitutional issues rather brusquely with the suggestion that justification for the new Ministries was a matter for the Government, which must shape the mechanism of Government to suit its purposes and policies. That such a dictatorial claim should pass unchallenged illustrates the weakness and shallowness of the debate, and although Mr. Butler quoted Dr. B. Crick's *The Reform of Parliament*†, that book in itself shows up the superficiality of the debate. Indeed, the whole debate illustrates the correctness of much of Dr. Crick's arguments, and the book especially indicts the Government's refusal to face the constitutional issue.

Early in his book Dr. Crick deals specifically with this issue of the continued strengthening of the Executive and its implications. While from 1900 until 1960 the number of Cabinet Ministers fluctuated below the level of 19 which it reached in both those years, it never exceeded that figure. During this period the number of other Ministers doubled from 10 to 20, and junior Ministers increased from 15 to 35. Although this was offset by a decrease in Royal Household appointments from 16 to 9, the total rose from 60 to 83—the number of M.P.s in the Government rising from 33 to 65, while the number of Parliamentary Private Secretaries increased from 9 to 36. There were thus in 1960 some 101 M.P.s involved in the Government compared with 42, and it is thus clear that the

\* *Machinery of Government Bill*. Pp. ii+7. (London: H.M.S.O., 1964.) 1s. 3d.

† *The Reform of Parliament*. By B. Crick. (London: Weidenfeld and Nicolson, 1964.) 36s.

increase with the formation of the present Government merely marks a tendency which has characterized the whole of the past sixty years.

The actual figures in the Machinery of Government Bill and the composition of the present Government, which has been largely responsible for the present concern, are not material, but it is worth noting that at the Committee stage in the House of Commons on December 10 the Attorney-General gave a figure of 137 for office holders in the present administration, of whom 116 are among the 317 supporters of the Government in the House of Commons. In the House of Lords on December 21 the number in the House of Commons was put at 122, including 31 Parliamentary Private Secretaries. That may not be a new situation, but with almost 40 per cent of the Government party in the House of Commons directly involved in the Government, the implications call for reconsideration.

The constitutional issue was not explicitly discussed at the Committee stage on December 9 nor when the Bill received its third reading in the House of Commons on December 10, the main criticism centering on the functions or the need for the proposed new Ministers. As might be expected, the constitutional issue figured more prominently when the Bill reached the House of Lords, both at the second reading on December 15 and in Committee on December 21. The Earl of Longford, in moving the second reading, admitted the importance of this constitutional issue, at least by implication, when he referred to the possibility that the Government might be acquiring too large an influence over Members of the House of Commons. While deprecating any idea that the House of Lords should attempt to set the limit, he conceded that there was obviously some limit to the number of Ministers that it is desirable to appoint in relation to the number of Members of Parliament.

Strong support for the view that the Bill was fundamentally a constitutional Bill came from Lord Dilhorne, Lord Morrison of Lambeth (who thought that the growth in the number of those in the House of Commons who could not speak and vote freely was unhealthy) and Lord Alport, though the Earl of Longford's reluctance to dogmatize on issues primarily concerned with the House of Commons was generally shared. Only the Lord Chancellor seriously argued that constitutional issues were not involved, but his defence was unconvincing, and earlier in his speech he indicated that the previous Government had also been careless on this matter, as Dr. Crick has shown so well in his book. The major feature of the Committee stage, however, was the acceptance by the Government of an amendment by Lord Dilhorne to change the title of the Bill to "Ministers of the Crown Bill", thus bringing it into line with the very similar Ministers of the Crown Act of 1937. This amendment was accepted by the House of Commons on December 22 and the Bill received Royal Assent as the Ministers of the Crown Act, 1964, on December 23.

Dr. Crick believes that this situation whereby the governing body gains in executive power presents grounds for serious concern. "A modern Prime Minister", he writes, "now has a patronage beyond the wildest dreams of political avarice of a Walpole or a Newcastle", and he directs particular attention to the increase in the number of Parliamentary Private Secretaries—an increase which he does not regard as justified by the loss of prominent back-benchers, when much of the most effective Parliamentary control of the Executive takes place not in the

official proceedings of Parliament but in the committees of the Government party itself.

Dr. Crick is thoroughly realistic, and two of the outstanding features of his book are the clarity with which he discusses this question of control of the Executive and the way in which he demonstrates the reluctance of the House of Commons itself to face the real issue—a feature which characterized the debate on November 19 just as much as earlier debates. The full weight of his argument is in support of strengthening the critical capacity of the House of Commons against the Executive, and he demonstrates the absurdity of any fear that this would necessarily weaken Britain's system of Cabinet Government. Equally important, he shows how mistaken is the common belief that the prime function of Parliament is to check or overthrow a Government: its prime function, on the contrary, is to put relevant facts and issues before the electorate which does sit in judgment on Governments. This critical and informative function is even more important than when Bagehot discussed it as the fourth main function.

It is essential that Dr. Crick's point should be clearly grasped if the Government's proposals for changing the structure of Government are to be assessed fairly and impartially. This is also true if sound proposals are to be made for meeting the difficulties arising out of the growing complexity of public affairs to-day and in determining the most effective means of bringing expert advice to bear whether in scientific or technical matters or in any other sphere. Dr. Crick is convinced that Parliament as well as the Executive needs to be better served in this respect, and his discussion bears very pertinently on two present issues. The first is the place and use of the Parliamentary Question; the second is the payment of Members of Parliament. Both are closely interlocked with the fundamental issues involved in the relation between science and Parliament and science and Government.

On the second issue, Dr. Crick argues convincingly that the first step, before Members' salaries are raised, should be to provide from public funds the essentials, such as secretary, office, postage, telephone and travel, that they require if they are to do their job efficiently. Salaries would still need raising, but this could perhaps be done selectively. As it is, the rejection of the recommendations of the Lawrence Committee regarding facilities, coupled with the increase in the proportion of the Government party involved in the Government, carries sinister implications. These the Government would be wise to dispel by positive measures, thus making up for its blatant brushing aside of the constitutional issues implicit in the Machinery of Government Bill.

On the issue of Parliamentary Questions, Dr. Crick is equally critical of the inertia or blindness of the House of Commons itself. He refuses to accept that shortage of Parliamentary time is any adequate explanation. The real difficulty is the refusal of the House of Commons to put first things first, and he is particularly severe on the missed opportunities in the debates of March 15 and August 1, 1963. He believes, for example, that if the existing Question Time was realistically used it might be a most effective means of controlling the Executive, and that the House of Commons has only itself to blame for allowing the period to shrink well below the full hour.

Here Dr. Crick takes his stand with Mr. D. N. Chester and Miss N. Bowring as opposed to Mr. S. A. Walkland in his recent article "Science and Parliament" in *Parlia-*

mentary Affairs for the Summer and Autumn of 1964. Mr. Walkland was discussing more particularly the origins and influence of the Parliamentary and Scientific Committee, but challenged the view that the Parliamentary Question could have any educational influence so far as science or technology is concerned. He seems to assume that such questions might be used to assess or criticize the technical basis of particular decisions or to probe official policy, but it is scarcely conceivable that such could ever be the intention. They could indeed bring to light issues or questions of fact that have been neglected. However, short of a revolution in the facilities or accommodation provided for Members of Parliament, it is most improbable that the Parliamentary Question by itself could do anything to check the increasing disparity between Parliament and the Executive in the matter of advice with which Mr. A. Albu, chairman of the Parliamentary and Scientific Committee, is much concerned. Mr. Albu, like Dr. Crick, believes that members have the remedy in their own hands and that no Government would be able to resist determined pressure from a sufficient number for the supply of more information and adequate research services to Members of Parliament. Nevertheless, Dr. Crick's examination scarcely justifies Mr. Walkland's pessimism, though it must be admitted that the way in which questions in Parliament have been used since a Ministry for Science was created does afford some justification. The extreme triviality and time-wasting character of many of the questions are well calculated to bring Parliament into discredit, but demonstrable abuse is not evidence that wise and effective use is not just as possible. Lord Mancroft's firm advocacy of the Parliamentary Question as a really effective weapon in both Houses, in the debate on the Address in the House of Lords on November 10, should not be overlooked, nor should the publication by D. N. Chester and N. Bowring, *Questions in Parliament* (Nature, 198, 321; 1965). Possibilities for good as well as for abuse need to be examined in due perspective, and while Dr. Crick never attempts to outline any scheme of Parliamentary reform he indicates what needs to be done to assess the adequacy or shortcomings of any particular proposals and the criteria which any satisfactory scheme should seek to satisfy.

His point that Parliament serves primarily to inform the electorate, not to overthrow Governments, is of cardinal importance; as a corollary, while a Government exists to govern, strong Government needs strong—but that does not mean factious—opposition. Government, he points out, must plan and must control finances, both in broad terms and in detail, but Members of Parliament are elected to serve their country, their party and their constituency, not themselves. Controls on any Government are all ultimately political, and in actual fact no Government can be responsible, or be held responsible, for every error or act of maladministration, nor will the House of Commons itself ever be able to look at everything that needs attention.

That much understanding of the political process is fundamental before approaching the question of technical and expert advice, but Dr. Crick comments also that much of politics is the art of being present at the right time. It is also worthy of note that he gives a reasoned and impressive rejection of the idea of an Ombudsman at present being considered by the Government, which is implicit in his assertion of the distinctive character of British Government and politics. In the present context of the Ministers of the Crown Act, the refusal to provide

Members with accommodation and facilities means that the proposals take on implications which would make the Government seek more distinctively British means of providing safeguards against administrative abuse. Here a remark of Dr. Crick is pertinent: "If anything useful and significant is to be done in a free society, it must be done publicly and in such a way as to consult, involve and carry with it those affected".

The main constructive proposal that flows from Dr. Crick's study is exactly in line with that which emerges from the studies of Mr. Albu and Mr. Walkland. Apart from emphasizing the value of the House of Lords in relieving pressure on the House of Commons in certain ways, Dr. Crick suggests that a rational use of specialist committees might provide an effective means for the House of Commons to fulfil more particularly its critical and educational functions. This has been convincingly demonstrated by the way in which the Select Committee on the Nationalized Industries has functioned. Mr. Walkland suggests, but much more diffidently, the establishment of a Select Committee on Scientific Policy, possibly to replace the Parliamentary and Scientific Committee, to whose influence he seems inclined to attribute less weight than is really due. However, the reality of this issue of power and influence is unmistakable, and it is too important to be discussed here and will be more appropriately considered in the context of the Science and Technology Bill and the actual functions of the new Ministries. For the present it must suffice to add that Mr. Walkland builds his hopes partly on the attraction into political life of more representatives of those professions whose attitudes are embodied in the Parliamentary and Scientific Committee. The improvement in the salary of members of Parliament might well act in that direction as he suggests; an improvement in facilities and accommodation is more likely to be decisive. Over and above either, however, the position of science in relation to Government and the structure of advice are likely to be critical, if not determining, factors.

## TWO CULTURES IN ACTION

### Science and the Shabby Curate of Poetry

Essays About the Two Cultures. By Martin Green. Pp. xiii + 159. (London: Longmans, Green and Co., Ltd., 1964.) 25s. net.

**E**VEN more than a discussion or critique, *Science and the Shabby Curate of Poetry* is a consequence of Lord Snow's "The Two Cultures". That lecture induced Mr. Green, who was then teaching English in the United States, to take mathematics courses at Harvard and the Massachusetts Institute of Technology, physics at Boston and later, on his return to England, to attend lectures at Cambridge in biochemistry and the history and philosophy of science. The present book sets forth the reflexions inspired by Snow's lectures and Mr. Green's subsequent experiences, including a year teaching English in a college of advanced technology. The outcome could have been a book of outstanding interest for, as this approach indicates, Mr. Green, while accepting Snow's thesis in outline, is entirely unbiased, though his primary concern is with the aspects of the subject which constitute a problem for the literary man. Snow's argument is treated fairly but not uncritically: however, it is curious that in almost his first paragraph Mr. Green shows that he has entirely missed what Snow had to say about the bearing of the two cultures on the gap between the rich and the poor countries.

These high expectations are unfortunately sadly disappointed. Mr. Green does not display Dr. Leavis's delightful talent for making the comprehensible incomprehensible, and there is too much careless writing, if not jargon, for either lucidity or forceful exposition: the general style of the book and the use of italics convey an impression of patchwork that is distracting and does not make easy reading. Mr. Green has grasped Lord Snow's essential message, but his attempt at further interpretation and application is scarcely effective or felicitous. He begins with a firm defence of Snow's thesis against Dr. Leavis's attack, in which he recognizes that science itself is an expression of human creativity, but one which requires more generous development if it is to make its full contribution to culture. He then discusses an essay by Prof. Trilling which he regards as far more stimulating and constructive than the outburst by Dr. Leavis. He regards the contribution which science has to offer as far more constructive than that which literature usually offers to-day, and while he suggests that more humility and realism about educational problems are to be found among scientists than among humanists, it is something of a paradox for him to state that we should be more concerned with how to make training in literature narrower and more logically astringent than to make training in science broader.

There may be two opinions also as to the extent to which in the past fifty or a hundred years both science and humanism have produced a greater literature than ever before—though it is probably true that our culture never lacks an integrated body of intellectual experiences, that includes both the scientific and the literary categories. It is when he is concerned more specifically with exposition and interpretation that Mr. Green is most disappointing: the achievement does not measure up to his aim and this is, at least in part, a matter of poor technique. He obviously grasps the root of the problem in education, the need for university teachers to be humanists and for the humanist to have some understanding of the world in which he lives.

The value of Mr. Green's book lies in its stimulus to thought, in the way in which he sets other minds examining imaginatively some of the problems which he brings to light. No essay on even a particular aspect of communication could hope to have any real effect unless a high standard of effective communication was set by example. Here, the argument is too often left loose, unconsolidated in the distraction of jargon. If Mr. Green had considered more carefully the reader he is addressing, his comments on Snow, on Leavis, and on Trilling, his accounts of his university courses and teaching experience, his survey of scientific exposition, could scarcely have failed to coalesce into a brilliant, suggestive and satisfying account. But for that a higher price must be paid in discipline as well as in an imaginative understanding of his readers.

R. BRIGHTMAN

## PRIMITIVE SYSTEMS OF MOVEMENT

### Primitive Motile Systems in Cell Biology

Edited by Robert D. Allen and Noburo Kamiya. (Proceedings of a Symposium on the Mechanism of Cytoplasmic Streaming, Cell Movement, and the Saltatory Motion of Subcellular Particles, held at Princeton University, April 2-5, 1963.) Pp. xix + 642. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1964.) 157s.

**D**URING April 1963, nearly one hundred scientists carrying out research in the biological field gathered at Princeton University to discuss the subject of primitive motile systems in cell biology, and this book comprises

thirty papers of the symposium and edited versions of discussions which followed their verbal presentation. Each paper was discussed separately, and four groups of topics which make up the four parts of the book were given "free discussion" by experts invited to make authoritative comments on the main topics.

In an introduction, the editors indicate that "primitive motile systems" include pseudopodial, ciliary and flagellar types of motion, the gliding of cells, the streaming of cytoplasm, the movements of chromosomes in cell division, the contraction of myonemes, the saltatory movements of cytoplasmic inclusions and some other kinds of movements in the cells of plants and animals. Despite great improvements in methods of investigation which have arisen out of technical advances, the basic mechanisms underlying these various kinds of movement have long remained obscure. Concepts such as gel contraction have appeared attractive but proved practically unacceptable.

The most fundamental kind of motion seen within living cells, the erratic zigzag displacements known as Brownian movement, occurs at molecular level, whereas saltatory motion involves cytoplasmic particles of very much greater size. Cytoplasmic streaming also involves visible particles, but these are grouped and move in unison as if transported by the flowing movements of the ground cytoplasm. Amoeboid movement has been regarded as a special kind of protoplasmic streaming in which locomotor organs (pseudopodia) are formed and alternately disappear, having little in common with the sort of cytoplasmic streaming which is seen in plant cells. Diversity of movement is enhanced in more highly organized motile systems involving cilia and flagella. All such forms of motion are produced by forces which are described as contractile, electrical, osmotic and so forth and which must have their sites localized objectively by direct observation. A further problem which is explained by the editors is the determination of the nature and availability of the chemical fuel—whether it is invariably adenosine triphosphate (ATP), how it is used and how withheld during cellular inactivity, and of what units it is composed.

In the introduction to Part 1 of the book, which deals with cytoplasmic streaming in plants and Myxomycetes (Mycetozoa), K. V. Thimann states that this kind of movement involves ATP, which produces characteristic effects when injected into living cells—causing the Myxomycete plasmodium to liquefy, inducing the cytoplasm of amoebae to flow away from the site of injection, stimulating streaming in *Acetabularia* and reactivating sperm tails after storage in the cold. Present also in Myxomycetes is a myosin-like protein capable of acting like the enzyme ATPase, stimulated by calcium in an effect which is antagonized by magnesium. Light, especially if it is blue, alters protoplasmic viscosity and there are ionic effects and other effects of a physiological nature. There is also evidence that streaming in Myxomycetes derives from anaerobic processes, and in plants it will continue for long periods in an atmosphere of nitrogen. Opinions concerning the mechanism involved converge on the importance of a sol-gel interface, which in amoebae is constantly breaking down and re-forming.

Hayashi considers the cortical gel layer in cytoplasmic streaming, concluding that rotational streaming in cells of Characeae ceases when this layer is destroyed by any means and recommences when it is re-formed. In discussion, the extreme thinness of the layer was indicated and the fact was disclosed that what is important in streaming is an organized inner surface and not the thickness of the layer. Asked how the cortical gel can be distinguished from endoplasm, Hayashi made the point that the former is stationary and the latter moving. Asked if the difference between these two parts is a matter of aggregation, he replied that they are structurally stable and different in function but probably transformable,

one from the other. Once the cortical gel layer is damaged it can no longer produce streaming, and the essential requisite is probably the organized inner surface of this layer.

In the introduction to Part 2, which is concerned with cytoplasmic streaming and locomotion in free-living amoebae, P. P. H. De Bruyn indicates that although we still do not know how an organism without visible locomotor organelles moves, various ideas have been rejected—that surface tension is responsible for amoeboid movement, that movement is due to elastic recoil from tension, that gelation itself is the cause of cytoplasmic contraction. It is suggested that terms borrowed from colloid chemistry may have been detrimental in some respects: the terms 'sol' and 'gel', 'solation' and 'gelation', serve to compare visible changes but do not tell us much about changes in the cytoplasmic proteins that are responsible for cytoplasmic movements, and it might be helpful to revert to the terms 'endoplasm' and 'ectoplasm'. The term now used to denote the motor force in cytoplasmic movement is 'contractility', and we have to remember that the contractile materials are not localized but are widely distributed throughout the cell. In amoeboid organisms there is morphological evidence of fibrillar organization, and the vital question is whether or not contraction can be localized in the fibrillar components. Are these invariably present when contraction occurs or are they formed when the need arises from a three-dimensional molecular reticulum?

Leucocytes of the blood form an interesting series. The lymphocyte moves like a monopodial amoeba, but in the granulocyte or macrophage this type of movement gives way to the more depolarized type and is accompanied by the properties of phagocytosis and pinocytosis, a development which points to a developmental effect on internal molecular architecture. Later on, the macrophage may develop into a fibroblast with limited motility but a marked ability to form fibres. Such changes must be accompanied by profound alteration in the morphoplastic or contractile proteins.

Wolpert and colleagues prepared a specific antibody against isolated surface membrane of an amoeba, labelled it with fluorescein to mark the surface, observed its behaviour during locomotion, and concluded that the surface flows forward during movement. This surface membrane seems to have a passive role in locomotion, suggesting that the forces which cause movement must reside in the cytoplasm. An isolated cytoplasmic fraction showed motility similar to that seen in intact cells, and induction of motility seems to be ATP-determined and sensitive to temperature. This fraction is capable of gelation streaming and syneresis, and electron micrographs of the gel resulting from syneresis show oriented fibres which may be responsible for motility. This paper produced lively discussion, and Goldacre expressed his views on the mechanism and control of amoeboid movement, proceeding from the familiar general view, based largely on the work of Pantin and of Mast, that locomotion in an amoeba is the result of contraction of one end of a tube of 'plasmagel' which encloses 'plasmasol', to his own opinion that in *Amoeba proteus* the motor mechanism resides in the rear end ('tail') rather than the front or advancing end. This region behaves like cytoplasm into which ATP has been injected, and a theory of amoeboid movement explained how a continuous supply of ATP could be provided at the cytoplasmic contraction in the amoeba's tail by membrane-plasmagel contact.

That this is not the final answer is shown by the findings of Kamiya that in capillary tube experiments an external hydrostatic pressure gradient can counterbalance endoplasmic streaming. So delicate is the balance that pressure change by less than 0.5 mm water can reverse the flow. A new pseudopod can be formed artificially by externally applied pressure gradients which force the endoplasm to flow, when the advancing end of an amoeba has a smooth

surface and often a hyaline cap and the rear end develops a wrinkled surface and a tail-like appearance. In free discussion, Allen, who gave a paper in Part 3 on cytoplasmic streaming and locomotion in marine Foraminifera, contrasted the two main hypotheses, from contraction and tail contraction, and produced some highly technical discussion, which will prove heavy going to all but the specialists in this mechanism.

Part 3 deals with cytoplasmic streaming, locomotion, and the behaviour of specialized amoeboid cells such as the pseudopodia of sea-urchin larvae, cells involved in inflammatory processes, neurones, filapodia and axopodia. In his introduction to this section, D. Marsland discusses briefly the two main types of hypotheses in respect of amoeboid movement, tube-wall contraction and fountain-zone contraction dealt with by Allen. What is referred to as the Mast-Marsland tube-wall contraction hypothesis of amoeboid movement can be summarized briefly. The tubular plasmagel-plasmasol system of an amoeba is not to be regarded as an inert system. In a complex interplay of stimulation and response, any part of one physical system may be converted into the other. The entire system tends to be tubular and either unbranched or branched, but local changes may result in a variety of structural reorganizations. The lumen of the tube may become occluded by localized gelation at any point, or it may increase or decrease by alteration of the sol/gel ratio. The contractile tension in the wall may also increase or decrease generally or locally, or the wall may give way because of localized solation, allowing another branch (pseudopodium) to grow out. Contractile tension may be maximal in the rear of an active amoeba, but the organism must be allowed a latitude of variation in satisfying the complex requirements of locomotion.

In introducing Part 4, D. W. Bishop refers to a fascinated non-participant witnessing heroic efforts to unify a chaotic situation which might be better regarded as a parcel of processes. He argues that while an underlying basis for movement in many cells may be attributed to muscle-like proteins, it is perhaps not to be expected that a single operational process is functional at all times throughout a cell, regardless of the intricate and experimental state of the cytoplasm. He emphasizes the comments of others that control and regulation mechanisms may act variously and continuously throughout the amoeba's body. This part of the book deals with the motion of subcellular particles and with mitotic movements, and there is considerable free discussion. The whole book contains a great wealth of highly technical information, much of it experimental, about the numerous areas of research on primitive motile systems in protoplasm, supported by many references to the literature and enhanced by discussions. In spite of innumerable observations and numerous hypotheses, however, it cannot be said that clearer ideas have emerged than existed already, although there are many pointers to extensions of research for the specialist. This seems to be indicative of progressive increase in difficulties of interpretation as a result of technical advances which have favoured greater and more detailed observation of relevant minutiae.

BEN DAWES

## PHYSIOLOGY AND BIOCHEMISTRY OF HERBICIDES

The Physiology and Biochemistry of Herbicides

Edited by L. J. Audus. Pp. xix+555. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1964.) 110s.

THE replacement of mechanical by chemical energy as the principal mode of continuing the "controversy with weeds" alluded to by a certain bishop is now a widely accepted and welcomed fact of agricultural life.

Nearly all the herbicides in use to-day have been discovered by industry in the course of screening new chemicals for biological activity, an empirical approach that is unlikely to be superseded for a long time to come. Nevertheless, the biochemical and physiological approach is likely to be increasingly fruitful in exploiting more fully the potentialities of existing herbicides and designing new ones. Both in this context and as a contribution to a better understanding of the selective effects of herbicides on plants, *The Physiology and Biochemistry of Herbicides* is especially timely. In seventeen chapters by various authorities, it reviews the present knowledge of all the major aspects of the behaviour and mode of action of herbicides which have a bearing on the nature of their phytotoxic effects.

The book opens with a chapter by R. C. Brian on the history of the development of herbicides, their practical uses and modes of action in plants. This is followed in Chapter 2 by a review of methods of analysis and determination by V. H. Freed.

Chapters 3, 4 and 5 provide perhaps the centre of gravity of the book. Chapter 3, by A. S. Crafts, reviews the penetration of herbicides into various plant surfaces, their movement out of leaves and roots, local accumulation, binding, persistence and ultimate fate. The various transport pathways of different herbicides receive thorough treatment, and the great complexity of routes of movement, sites of action and modes of eventual detoxication is well brought out.

In Chapter 4, G. S. Hartley reviews the present knowledge of the behaviour of herbicides in the soil in terms of the various physical factors influencing their movement and action. Aspects considered include the diffusion of herbicides in the air and water phases of soil, their transport and dispersion in moving water, and the mechanism of their adsorption by clay and organic matter. This is an impressive attempt to provide a mathematical-physical framework within which the great complexity of behaviour exhibited by herbicides in the soil can be interpreted, and is especially welcome in view of the practical importance the soil-acting herbicides have now assumed.

In Chapter 5, L. J. Audus reviews the interactions between herbicides and micro-organisms in the soil and indicates the dominating role of bacteria in the detoxication of herbicides. There is a report of apparently unpublished work on the relation between structure in the phenoxy herbicides and the ease with which they are attacked by bacteria. Biochemical pathways of herbicide degradation and the effect of herbicides on various classes of micro-organism are also considered.

The next chapters pursue the theme of the action of herbicides within the plant. In Chapter 6, O. Kiermayer reviews the effect of auxins and growth-regulator herbicides on cell division and elongation. Ch. J. Gorter and W. van der Zweep in Chapter 7 review the morphogenetic effects of growth-regulator herbicides. In Chapter 8, F. T. Addicott and H. R. Carns consider abscission responses to herbicides; and in Chapter 9, D. J. Wort reviews the effect of herbicides on plant composition and metabolic systems. In a further chapter, he also considers the effect of sub-lethal concentrations of 2,4-D on plants with and without the addition of minor nutrient elements.

In their second contribution, H. R. Carns and F. T. Addicott in Chapter 11 review the effects of herbicides on various endogenous regulator systems, with an interesting discussion on the role of unsaturated lactones in the damage caused by growth-regulator herbicides. In Chapter 12, R. C. Brian considers the effect of herbicides on biophysical processes in plants, and concludes that, of these, changes in permeability brought about by the use of growth-regulator herbicides are the most likely to result in morphological changes. In Chapter 13, J. van Overbeek summarizes the knowledge of the mode of

action of herbicides operating on the growth processes and photosynthetic activities of plants.

The next three chapters are devoted to aspects of the selective effects of herbicides. E. Åberg in Chapter 14 considers the influence of stage of development, vigour, previous history and variety on the response of crops and weeds. In Chapter 15, K. Holly reviews selectivity in relation to chemical structure, spray retention and penetration into plant surfaces and soil factors which influence the soil-acting herbicides. He stresses the relative neglect of the study of mechanisms of root uptake. R. L. Wain in Chapter 16 ends this section with a review of the behaviour of herbicides within the plant in relation to their selective effects. The book concludes with a final chapter by H. Linser on the design of herbicides in the light of present biochemical knowledge, in which he stresses the need for more knowledge of the sites and modes of action of herbicides and the special metabolic characteristics of species on which selectivity can be based.

The individual fields are on the whole well separated from each other and between them provide an impressive overall picture both of the great range of interactions between herbicides and plants and of progress made in their unravelling.

Despite the vast amount of experimentation on natural and synthetic auxins, the primary sites of action of growth-regulator herbicides such as 2,4-D are still not known; nor are the reasons for the differing reactions of the Gramineae and dicotyledonous plants well understood. These and many other problems remain. The field is an active one and is also likely to reflect the increasing significance of the soil-acting herbicides. As both a source of reference and a commentary, this volume will be widely welcomed by advanced students and research workers to whom it is primarily addressed. There is an index of authors of bibliographic references and a subject index. There are a few misprints, such as Knüsh for Knüsli on p. 17 and some apparent confusion between pyridiazine and pyridazine on p. 492.

P. J. BOYLE

## BRITISH CENTIPEDES

### Centipedes of the British Isles

By E. H. Eason. Pp. x+294+5 plates. (London and New York: Frederick Warne and Co., Ltd., 1964.) 63s. net.

CENTIPEDES are among the commonest animals on the surface of the Earth. European soils, woodland, grassland and arable alike, support on the average more than one hundred of these animals per square metre and yet many people are scarcely aware of their existence. Centipedes have never been a fashionable group, but there will be many for whom the publication of a British monograph will have been an eagerly awaited event. Once again our small collection of British Faunas has been added to by an amateur, that is to say by one who combines his natural history with other professional duties. There is nothing amateurish about *Centipedes of the British Isles*; it is an authoritative account of the entire British fauna. Forty-four species are described with great clarity and meticulous attention to detail.

Each species is accorded about four pages of text, of which at least one, frequently two, are devoted to very clear line drawings that adequately illustrate the text. In addition, there are five excellent photographs by Dr. Manton. Everything necessary for reasonably certain diagnosis of adults is set forth. Unfortunately, it is a little difficult to find one's way about the book; there is no distinction in the index between the most pertinent page references to the species and incidental mentions in the body of the keys and in the general introductory matter. There is some advantage in having the spinulation

tables for each species of *Lithobius* gathered together in an appendix, but they would be better with species headings instead of just numbers.

The immature stadia of one species of *Lithobius* are described in detail from the author's own work and more general remarks on the stadia in other groups are included. Although references are given for other life-history investigations, the author does not include much detail from these. Since he mentions that such authorities as the late K. W. Verhoeff have been misled by sub-adult specimens, he might have used a little more space to help others not to make the same mistakes. For example, the post-larval *Lithobius forficatus* with four teeth on the coxosternum of each maxilliped might be mistaken for a smaller species which does not run down in the key.

Our knowledge of the distribution of centipedes in Britain is still sadly incomplete—witness the lists of county records at the end of each species description. This will give much encouragement to those for whom the prospect of a new county record is exciting. In a general chapter on distribution, the paucity of the Scottish and Irish faunas is noted and species with restricted distributions are mentioned. It would have been helpful had the species concerned been listed; for example, one cannot discover at a glance which are the three littoral species without glancing through the notes on all forty-four. A foretaste of the interest which will accrue from detailed mapping of distribution is available for *Lithobius variegatus*. This must be our most interesting centipede and appears to be endemic to Britain. Dr. Eason noticed that the existing records were all from the west side of the 38° F January isotherm, and his collecting in some critical localities confirmed this pattern of distribution.

One cannot expect clear statements of habitat preferences when such a small number of people have been able to recognize species. As a consequence most of the habitat notes are disappointingly vague. Two of the more explicit notes refer to *Lithobius calcaratus* and *L. crassipes*—"the majority of records... are from woodland" and "common in moorland and mountainous country as well as in grassland and woodland". I think I detect here a bias towards woodland for *calcaratus* and open land for *crassipes* which is the very reverse of some published habitat notes. However, such impressions concerning distribution are necessarily very subjective. By providing the ecologist and naturalist with reliable means for diagnosis, Dr. Eason has ensured that more objective descriptions of ecological distribution will be possible in the near future.

J. G. BLOWER

## USER—COMPUTER LANGUAGE

Numerical Methods and Fortran Programming with Applications in Engineering and Science

By Daniel D. McCracken and Dr. William S. Dorn. Pp. xii + 458. (New York and London: John Wiley and Sons, Inc., 1964.) 57s.

TO quote Sir Edward Bullard on the subject of the language of machines: "Most machines do only a few things, and the problem of telling them what to do is not difficult. An electronic computer is an unusual machine in that it can undertake a very wide range of operations. This variety of possible behaviour raises very severe problems of communication between the user and his machine and has led to the development of the art and profession of computer programming...". *Numerical Methods and Fortran Programming* deals with two associated topics—the problem of communication between the user and the computer mentioned by Sir Edward Bullard and the prior business of converting mathematical

models into a step-by-step form ready for communication.

In fact, three main tasks must be undertaken when solving a physical problem using a computer. The problem must first be given a mathematical model which illustrates the crux of the matter to be solved. Secondly, having decided on the model, a method of numerical investigation is chosen and the problem is coded, that is to say, a list of instructions in some language is prepared, which will eventually uniquely direct the computer to perform what calculation is required. Thirdly, the programme is fed into the computer and 'de-bugged', and eventually the required results are obtained. Put in this way, the book covers the second task outlined here adequately and very well.

An important point which is sometimes missed, and which is scarcely mentioned in the book (perhaps because it is an introductory work), is that when one approaches the computer with a programme, the computer is already armed with a very large programme, the compiler, which is waiting to deal with coding work. The compiler translates the programme as language into a form which the computer can deal with, and it is only when the whole programme has been translated in this way that the real business of computation can proceed.

Some of the art and profession of computer programming mentioned by Sir Edward Bullard is to do with spelling and the grammar of the language, but some of it is concerned with getting to know what the compiler will make of a particular piece of coding.

In these days of ever increasing use of electronic digital computation, the book will satisfy two main requirements. For mathematicians, physicists and engineers, not in any way familiar with a computer language, four chapters and an appendix take the subject of a particular language, Fortran II, from the fundamentals, through the basics of programme design to the use of sub-routines and format procedure for input and output. Interleaved between these chapters are six other chapters dealing with the numerical analytical detail which one must tackle sooner or later if one is serious about using computers to solve serious problems. The numerical analysis topics range from power series, iteration for the roots of algebraic equations, numerical integration, simultaneous linear equations, to the integration of sets of ordinary and partial differential equations. The material of the two main topics is matched, so that the reader has usually seen enough of the particular language to cast his numerical analysis into language, and has usually seen enough numerical analysis to put his equations into a language that can be solved by a computer. Each chapter is followed by a good number of well-chosen exercises, answers to which are provided; but more important is the use made of 'case studies' which occur at the close of each chapter. The case study poses a practical problem on the material so far introduced and then carefully goes through the detail of its solution. While being useful to the extent that the reader is made to appreciate the necessity for intense attention to accuracy in detail, which is vital for successful computer work, the case studies may be too discursive for some readers and might well be missed on a first reading. Readers who begin to programme some examples, however, will find themselves going back to the detail for vital information.

For advanced undergraduates and for research workers in almost any field of science who intend using computers, this book will be welcome, particularly if they are aimed at an I.B.M. machine or at least a computer with a Fortran compiler; it must be said, however, that not all computers have one, and that some computers have rather poor ones. The book is well produced and makes an excellent general purpose introduction to the whole business of getting answers from digital computers.

G. BLACK

## "THE FRIEND OF MANKIND"

### A PORTRAIT OF COUNT RUMFORD

Substance of a Friday Evening Discourse delivered at the  
Royal Institution on November 13, 1964

By A. H. EWEN

THE year 1964 marked the one hundred and fiftieth anniversary of the death of Sir Benjamin Thompson, Count Rumford. During his lifetime his colourful career in the United States, England, Bavaria and France as a soldier, statesman, scientist and social reformer made him one of the best-known names of his generation. As a scientist he achieved international renown, and was awarded the Copley Medal of the Royal Society for his contributions to the science of heat; in both Europe and the United States his name was literally a household word, thanks to the Rumford stoves and Rumford roasters which were all the vogue in both aristocratic and middle-class homes; his cure for the domestic evil of smoky chimneys added a new word to the English language—to 'rumfordize'—while the famous Rumford soups, prepared according to his economical recipes in public kitchens, were well known to the poor of many countries.

But to-day Rumford's name and his work have lapsed into obscurity, and even into disrepute. Both the importance of his contribution to the science of heat, so strongly stressed by Tyndall, and the originality of his observation of convection currents have been questioned. Despite President Franklin Roosevelt's dictum that Rumford together with Benjamin Franklin and Thomas Jefferson are the three greatest minds that the United States ever produced, his reputation in America suffered a severe blow from the discovery in the 1930s of positive proof of his spying activities on behalf of the British in the American War of Independence. This revelation of his disloyalty to the Republican cause has led some recent biographers, for example, J. A. Thompson (1935) and Sanborn Brown (1962), to assert that his present obscurity is fully deserved because of his dishonourable and anti-social conduct, and they point to his difficulties in Bavaria and England as evidence of his arrogant and dictatorial personality, which in their view not only disgusted and antagonized his contemporaries but also made him impossible as a colleague.

This charge of dishonourable conduct is primarily based on Thompson's work as an intelligence agent in the War of Independence; but on this point his American critics fail to appreciate that their unfavourable judgment of his conduct is a purely subjective opinion. At this period Thompson held a commission as a major in the New Hampshire Provincial Regiment, and his activities can equally well be interpreted as the skilful execution of a highly dangerous mission which he undertook in obedience to the orders of his superior officers. Thompson did not conceal his unwillingness to join in the rebellion against British rule, and however unwelcome the discovery of his spying may be to American opinion, willing obedience to the orders of superior officers cannot justifiably be termed dishonourable.

Nor can the difficulties which he experienced in Bavaria be simply attributed to his own faults of character. Acting as the executive Minister of the Elector Charles Theodore, Thompson embarked on a carefully planned campaign for modernizing the army and abolishing mendicancy. Before putting his scheme into operation he made full use of his scientific ability to determine the best material for army uniforms, the most nutritious and economical diet for his work-people, and the most efficient design for fuel-saving cooking-ranges; in all his scientific

work he was always more concerned with finding a scientific answer to a practical problem than with pursuing a disinterested enquiry into the secrets of Nature. This closely integrated group of reforms constitutes one of the first instances in history of the application of scientific method to the solution of social problems, and in his emphasis on the technological aspects of applying scientific knowledge to the common purposes of everyday life Thompson was a true pioneer.

But it was not the merit or the method of his reforms that aroused opposition so much as their political implications, and this opposition took the form of attacks on his personal character and integrity. One of the chief causes of contention was his creation, on swampy ground on the banks of the River Isar, of a public park, known as the English Garden, for the benefit of the citizens of Munich. This operation was completely successful, but brought a major clash with the Town Council, who resented the political popularity which accrued to the Elector from the creation of the park. Another cause of trouble was his attempt to open commissioned rank to all classes of the community by founding a Military Academy which made education available even to the poorest; but this enlightened reform provoked the hostility of the privileged caste of aristocratic army officers. In both these instances it was the political implications of his reforms, not his defects of character or his methods of administration, that created his difficulties, and ultimately led to his withdrawal from active political life after the Elector had granted him a life pension, and created him a Count of the Holy Roman Empire as a reward for his services.

In the same way the difficulties which he experienced during his stay in England, when he was associated with the project of establishing the Royal Institution, were primarily political rather than personal. His outspoken attacks on the luxury and self-indulgence of the aristocracy, and their torpid indifference to science and scientific improvements, and his advocacy of social reforms such as popular technical education and the abolition of 'jobbery' in public administration, rendered him an object of suspicion to the Tory Government, who regarded him as a revolutionary agent, and refused to accept him as Bavarian Minister in London. He was excluded from Court, and rumours that he was a French spy were fostered by high Government officials. The satirical poet Peter Pindar reflects the prevailing hostility in his poetical "Letter to Count Rumford", in which he taunted Rumford with his exclusion from Court, decried his scientific work as quackery, and ridiculed his arrogance and self-conceit.

The cordial warmth of his reception in Paris during a seven-weeks visit contrasted sharply with the cold-shouldering which he had experienced in London. He was accorded precedence as a Minister, a distinction which had been denied him in London; his eminence as a scientist and a philanthropic pioneer was publicly recognized, and a personal attachment was formed with Madame Anne Lavoisier, the widow of the great chemist. Rumford had no hesitation in deciding to wind up his affairs in England, including his association with the Royal Institution, and to exchange the aloof hostility of London society, which showed little or no interest in science, for the more congenial atmosphere of the *bourgeois* society of Paris with its high regard for science.

But in France his rigid insistence on maintaining a strict neutrality in the conflict between France and Britain aroused the hostility of the strongly nationalist members of the Institute, who also displayed jealousy of his scientific work. After the failure of his marriage with Madame Lavoisier he purchased a property at Auteuil, where he lived in increasing isolation until his death on August 21, 1814.

Superficially, Rumford's persistent failure to achieve lasting social success and personal happiness in three such widely different countries as feudal Bavaria, patrician England and republican France would seem to be a decisive indictment of his own character. Although his American critics attribute this failure to his lack of moral principle, which they insist antagonized his contemporaries, it was, in fact, Rumford's rigidity of principle and unwillingness to compromise that caused his social difficulties. If he had been more pliable and less scrupulous, he could easily have adapted himself to the winds of political change, and he would then have escaped social isolation in his lifetime, and historical disrepute after his death. But he was never mercenary, and always resolutely opposed to 'jobbery'. Although he could have made a considerable fortune by the commercial exploitation of his scientifically improved heating appliances, he made his designs freely available for the public benefit.

An important influence in his life was the fact that he was always a 'foreigner'. In his native America his support of the British made him a renegade and an exile; in Bavaria he was a 'Yankee Interloper'; in England many thought that he was a German, and there was a widespread belief that he was a French agent; in France no one quite knew whether he was an American, an Englishman or a German, but he was certainly not a Frenchman. This lack of 'roots' created a sense of psychological insecurity, which he tried to conceal under a mask of excessive self-assertion, which his critics construed as arrogance and self-conceit.

But this foreignness was also a source of strength, as it enabled him to accomplish tasks which would never have been undertaken by a native of the country. Only a foreigner would have attempted to create an English Garden in the heart of Germany; only a foreigner would have succeeded in launching an enterprise like the Royal Institution in the middle of a major war and at a time of acute financial stringency.

But this bland disregard of his environment also made him an easy target for the attacks of his opponents; he was always open to the charge of lack of patriotism. For Rumford gave his loyalty to mankind as a whole rather than to any one single country. As a German newspaper once said of him: "Rumford is a citizen of the world in the great meaning of that word, for wherever Fate puts him, he acts with equal vigour. Not his own country, but the whole world, will one day erect his monument". That day has not yet come, and in the meantime the chief consequence of his lack of nationality has been that no country wishes to claim him and sing his praises.

The sheer diversity of his achievements as a soldier, statesman, scientist and social reformer inevitably prevented him from attaining the highest rank in any one single field, but in all these spheres of activity his work reached a high level of distinction. But Rumford's chief claim to fame is that he belonged to that very small group of men who have possessed the rare combination of imaginative vision and the administrative ability to realize that vision in a permanent and socially viable form. The proof that Rumford possessed this rare combination of qualities to a high degree is shown by the enduring vitality of his creations 150 years after his death.

Few men have bequeathed such a diverse set of benefactions to posterity. His endowments for the encouragement of science, which were very generous in proportion to his means, have borne notable fruit. The Rumford Medal of the Royal Society numbers among its recipients many of the world's greatest scientists. His emphasis on the technological aspect of science in his endowment of the Harvard professorship played an important part in the foundation of the Massachusetts Institute of Technology in 1865, when the first Rumford professor delivered the inaugural address.

The Royal Institution, "originally and chiefly my work" as Rumford once justifiably claimed, has made a contribution of outstanding magnitude to the advancement of science, both in the field of original research and in the sphere of scientific education. On his memorial in the English Garden at Munich, which has recently celebrated the one hundred and seventy-fifth anniversary of its opening, Rumford is described as "The Friend of Mankind", a title well deserved by his diverse contributions to human knowledge and human happiness.

## RECENT TRENDS IN THE LEVEL OF FALL-OUT CAESIUM-137 IN MAN

By DR. S. H. COHN, DR. E. A. GUSMANO and DR. R. A. LOVE

Medical Research Center, Brookhaven National Laboratory, Upton, Long Island, New York

**B**ODY-BURDENS of caesium-137 ( $^{137}\text{Cs}$ ) in the population reflect the level of fall-out from previous nuclear weapon tests. Since the  $\gamma$ -rays of  $^{137}\text{Cs}$ , as well as those of naturally occurring potassium-40, can readily be measured in people by use of the whole-body  $\gamma$ -spectrometer, many data have been adduced on the level of  $^{137}\text{Cs}$  in order to ascertain its distribution in the world, as well as its attendant potential radiation hazard<sup>1,2</sup>. During 1948-61 world-wide data on the levels of  $^{137}\text{Cs}$  in man, as well as in food, have been collected and reported by a United Nations Scientific Committee<sup>3</sup>. The  $^{137}\text{Cs}$  content of man increased continuously to a maximum in 1959, followed by a continuous fall during the period 1959-61. This article reports an investigation on ten adults for the period June 1960-September 1964.

Measurements of the internally deposited  $^{137}\text{Cs}$  and  $^{40}\text{K}$  were obtained with the Brookhaven whole-body counter. An 8-in.  $\times$  4-in. sodium iodide crystal detector used in a standard counting geometry previously described was

used<sup>4</sup>. The subjects (7 males and 3 females), ranging in age from 25 to 45 years, are all members of the scientific staff of Brookhaven. These people are all in good health and have not been exposed to radioactive contamination in the course of their normal work. A 30-min count was obtained from each subject at monthly intervals for the four-year period.

The  $^{137}\text{Cs}$  data are expressed as pc./g potassium, the conventional manner of reporting such data. (The primary advantage of this unit is that it tends to minimize the spread in values due to variations in body-weight.) The area under the appropriate spectral photopeaks of  $^{137}\text{Cs}$  (0.663 MeV) and  $^{40}\text{K}$  (1.46 MeV) was integrated with an IBM-7094 computer programme, and the absolute levels of the radionuclides determined by calibration against a phantom (REMAB, Alderson) containing known levels of a standardized solution of  $^{137}\text{Cs}$  and potassium. As a further check, the  $^{137}\text{Cs}$ -levels of five of the male subjects were calibrated against a standardized  $^{137}\text{Cs}$

Fig. 1. Body-burdens of cesium-137 in a selected population (1960-64)

solution obtained from the International Atomic Energy Agency and administered intravenously. The absolute  $^{137}\text{Cs}$  values obtained with this standard solution check quite closely ( $\pm 4$  per cent) with the calibration made with the phantom.

The profiles of the  $^{137}\text{Cs}$ -level in each of these 10 subjects are shown in Fig. 1. There was a continuous fall in  $^{137}\text{Cs}$ -levels from June 1960 until the spring of 1962, when the curves show an upward inflexion. From December 1958 until the autumn of 1961 the only reported nuclear detonations were the four small French detonations in the spring of 1960 and 1961. The  $^{137}\text{Cs}$ -levels continued to rise to August 1964. The mean  $^{137}\text{Cs}$ -level in August was 180 pc./g potassium, which corresponds to a dose-rate of 3 mr./y., or 2.2 per cent of that from natural radiation sources. The values of the most recent measurements in mid-September 1964 are lower in each subject than those recorded in August. It is necessary to continue these measurements to ascertain whether the maximum level was reached in August followed by the beginning of a downward trend. In each subject the increase in the  $^{137}\text{Cs}$  from the minimum point in early 1962 to August 1964 is approximately six-fold. The August 1964 mean  $^{137}\text{Cs}$ -level is more than 2.5 times the previous maximum mean value observed in 1959. This increase in the level of  $^{137}\text{Cs}$  is opposed by the normal biological loss of  $^{137}\text{Cs}$ . The biological loss of  $^{137}\text{Cs}$  from the major body compartment varies from 60 to 140 days and accounts in part for the spread in  $^{137}\text{Cs}$ -levels in the population<sup>5</sup>. Within this group there is a fairly consistent spread in values ranging from the male (E. G.) with the highest level to the female (M. H.) with the lowest level.

The most recent fall-out producing nuclear detonations occurred in the latter part of 1962 (Fig. 1). It has been predicted that with tests ending at the end of 1962, the maximum fall-out rate for strontium-90 would occur in 1964, while the maximum deposition of  $^{90}\text{Sr}$  under the

foregoing conditions would occur in 1967 (ref. 3). It appears likely that a similar pattern would hold for  $^{137}\text{Cs}$  (ref. 3). The level of  $^{137}\text{Cs}$  in food and consequently in man is a function of both the fall-out rate and the amount of accumulated deposit. The apparent maximum in the  $^{137}\text{Cs}$  body-burden noted in August 1964 suggests that the  $^{137}\text{Cs}$ -level of milk (the primary food contributor), and consequently of the human population, reflects the present fall-out rate. The fall in the level of  $^{137}\text{Cs}$  in the body during 1960-62 in the face of the rise in the cumulative pool of  $^{137}\text{Cs}$  on Earth further corroborates this dependence of body-burden on the rate of fall-out. Part of the fluctuation in the  $^{137}\text{Cs}$  body-levels as a function of time also undoubtedly reflects the seasonal nature of agricultural practices and afterwards the  $^{137}\text{Cs}$ -level in milk. The sharpest rise in  $^{137}\text{Cs}$ -levels appears in the spring of the year and is associated with heavy rainfall and return of cattle to the pasture.

The small population examined here reflects the level of  $^{137}\text{Cs}$  found in a large changing Brookhaven population counted during the same period. Further, the mean  $^{137}\text{Cs}$ -level of this larger Brookhaven population sampled was very close to the mean of a still larger United States and Western European population. For example, in early 1960 the average  $^{137}\text{Cs}$ -level of 73 Brookhaven personnel was 59.2 pc./g potassium, as compared with the mean value of a large population sample (2,800 people in the United States and Western Europe) of 60 pc./g potassium  $\pm 25$  per cent<sup>3</sup>. The variations in  $^{137}\text{Cs}$ -level have been shown to be surprisingly small over large geographical areas in the United States<sup>4</sup>. That this uniformity in  $^{137}\text{Cs}$ -levels, in fact, extends over the northern hemisphere is suggested by comparing the results of the present investigation with similar work recently carried out in England. Rundo<sup>6</sup> reported a mean for a group of approximately 13 adults of 25 pc./g potassium in April 1962, compared with a mean of 25.8 pc./g potassium at Brook-

haven. The most recent mean  $^{137}\text{Cs}$  value reported by Rundo in April 1964 was 150 pc./g (100–200 range), which compares closely with the value of 136 pc./g (68–250 range) obtained at Brookhaven at the same time. Both these investigations utilized very small samples, and cannot, of course, be extrapolated to determine the  $^{137}\text{Cs}$ -level in the American or Western European population, but the approximate levels of  $^{137}\text{Cs}$  and its pattern with time are clearly indicated. It will be of interest to follow these levels of  $^{137}\text{Cs}$  in larger population samples throughout the world to check on predictions of the  $^{137}\text{Cs}$  inventory and hold-up time for stratospheric fall-out and its rate of transfer to men. Whole-body counting data are valuable in this respect, as there are insufficient data to extrapolate from  $^{137}\text{Cs}$  food levels in order to predict future  $^{137}\text{Cs}$ -levels in man with accuracy. Adequate 'portable' whole-body counters now exist which would permit the collecting of data in parts of the world where at

present no permanent whole-body counting installations exist<sup>7</sup>. Use of these portable counters would greatly extend our knowledge of the distribution pattern of fall-out in man.

We thank Mr. M. Stravino and Dr. C. Constantinides for their assistance and collaboration.

## AN EXPANDING EARTH?

By DR. K. M. CREER

Department of Physics, University of Newcastle upon Tyne

**A**MONG the few geologists and geophysicists who have tentatively proposed that the Earth's radius has expanded by a factor of nearly two, Carey<sup>1</sup> has concluded from tectonic investigations that this large expansion has occurred since the Palaeozoic, while Egyed<sup>2</sup> has argued that a slow expansion of about 0.5 mm/yr has been going on throughout the Earth's life. An expansion of this magnitude cannot be accounted for by known physical processes<sup>3</sup>.

I became interested in the expansion of the Earth while using palaeomagnetic data to deduce the distribution of the continents in the upper Palaeozoic, using fibreglass shell models of the continents which could be slid over the surface of a 50-cm diameter globe<sup>4,5</sup>. It has been argued<sup>1,2,11</sup> that the present shapes of the continents are consistent with the supposition that they once comprised a complete outer shell of a smaller Earth. Usually these arguments have been supported by rough sketches.

### Palaeomagnetism and Expansion

Attempts have recently been made<sup>6–10</sup> to use palaeomagnetic measurements to detect changes in the Earth's radius. This is possible because one peculiar feature of all expansion hypotheses is that the area of continental material has remained constant while the bulk of the Earth has expanded. Hence the palaeoradius can be determined from measurements of the difference in palaeolatitude between two sites of known separation on the same continental block. At present the only data which are really adequate for this purpose are for Permian rocks from sites in Western Europe and Siberia, about 5,000 km apart. There is general, though not unanimous<sup>10</sup>, agreement that the data do not support an expansion as rapid as predicted by Carey since the Permian, but they are not sufficiently precise to confirm or reject a slow expansion as proposed by Egyed (Table 1).

### Palaeogeography and Expansion

The continents, down to the 500 fathom line where hypsographic charts show their steepest gradient, now cover about 30 per cent of the Earth's surface. This available sialic continental material might thus have covered a primitive Earth having a radius of about 0.55 of the present value. A simple model experiment could be carried out to investigate the fit by making 'Perspex'

shell models of the continents scaled and moulded to the curvature of the 50-cm globe and then remoulding these to the curvature of a 27-cm diameter globe, 0.55 times the size of the globe modelling the present Earth. These models of the continents would comprise pieces of a jig-saw to be fitted together on the surface of the 27-cm globe which they should cover. In fact, the experiment was carried out by making fibreglass shell models of the continents with great circle distances from a central point increased by a factor of  $0.55^{-1} = 1.82$  and fitting these together on the 50-cm globe. The fit obtained is illustrated in Figs. 1a and 2a.

To aid recognition, coastlines are shown rather than the edges of continental shelves. Most of the space between the continental outlines in the figures is occupied by continental shelf. There is considerable overlap of Patagonia and Antarctica. However, no pre-Mesozoic rocks have been found in Patagonia and it has been suggested that this southern part of South America has existed only since the Mesozoic. There is also an overlap in the region of the East Indies; but this is not apparent in Figs. 1a and 2a because they do not show the edges of the continental shelves.

Even if continental material did once comprise a complete outer skin, one should not expect a perfect fit because of the following sources of distortion: (1) That produced by the radial expansion method used. This could well be different from the way in which the shapes of the continents would be distorted if the Earth expanded. (2) That due to tectonic movements, mountain building and a variety of other geological processes such as erosion. This point is considered in a later section of this note.

The problem of judging the accuracy of fit by exact mathematical treatment is thus complicated by the large number of variables. Nevertheless, suppose we take a number of pieces of spherical shell, of about continental size and complexity of shape, the total area of which equals that of the sphere having their curvature. The probability of finding a fit as good as found for the model continents may be computed. This I am now doing.

Table 1

Ref.	Ratio of Permian to present radius	Method
Carey (ref. 1)	0.83	Tectonic studies
Egyed (ref. 2)	0.99 – 0.97	Palaeogeography
Cox and Doell (ref. 8)	0.90 ± 0.03	Palaeomagnetic
Ward (ref. 9)	0.94 ± 0.04	Palaeomagnetic
van Hilten (ref. 10)	0.83 ± ?	Palaeomagnetic

(1b)

(1c)

Fig. 1. To illustrate how the shapes of the continents are consistent with evolution on an expanding Earth. Radius of Earth in (a) is 0.55, in (b) 0.77 and in (c) 1.0 of the present radius

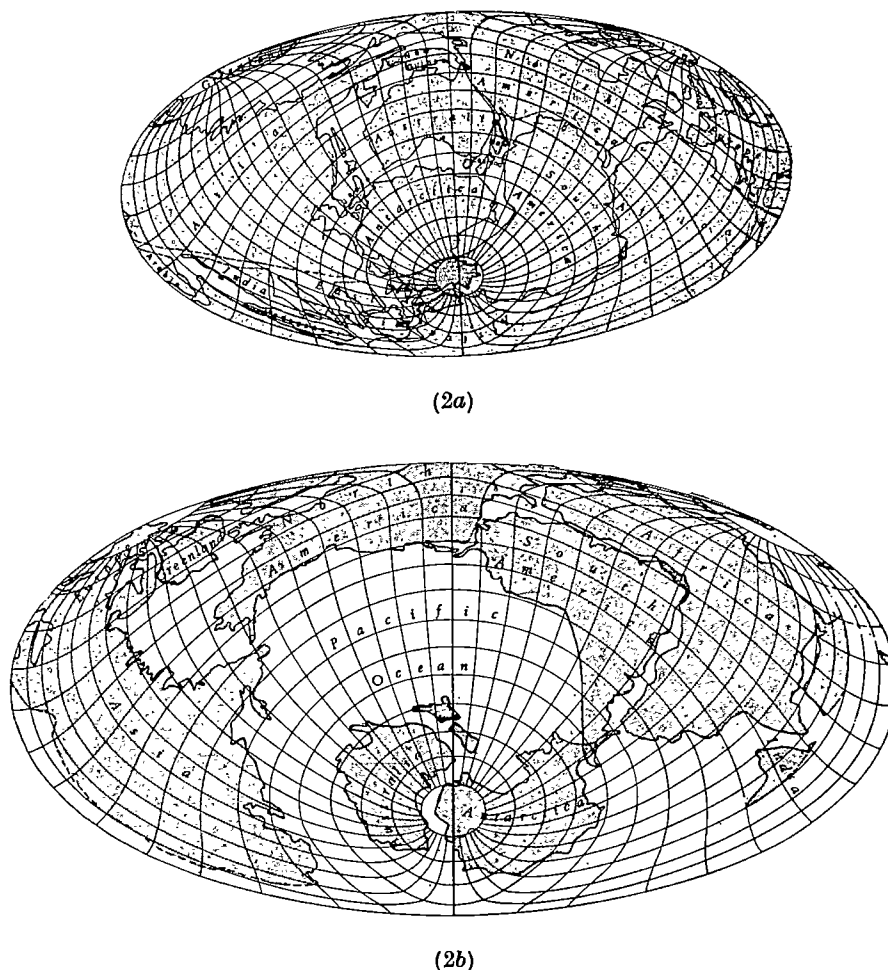

Fig. 2. To illustrate how Australia and Antarctica fit between eastern Asia and western America on an Earth the radius of which is 0.55 of the present value (a). On expansion of the interior of the Earth a U-shaped crack appears to have developed round the Pacific Basin. (b) illustrates Earth reduced to 0.77 of its present radius. (Note Figs. 1a and 2a and Figs. 1b and 2b respectively show the same continental distributions viewed from different angles and moved with respect to the grid)

At this stage, however, I have formed the impression that the fit of the continents on a smaller Earth illustrated in Figs. 1a and 2a appears too good to be due to coincidence and hence requires explaining. The simplest explanation appears to be expansion of the Earth, and one purpose of this article is to suggest that this hypothesis should be taken seriously.

#### Development of Pangaea

Some of the earlier workers in continental drift noticed that the profiles of the coastlines of the continents were such that they could be fitted together on an Earth of present radius to form a single supercontinent which they called 'Pangaea' (Fig. 1c). Recently it has been shown by precise methods<sup>12</sup> that the profiles of the continental shelves match even better than the coastlines.

To test whether the distribution of continents on a primitive Earth of little more than half the present radius is consistent with their grouping in Pangaea, a set of 'Perspex' shell models of the present continents on the 50-cm globe could have been remoulded to the curvature of an intermediate-sized globe, say 37 cm diameter. In fact, as before, the 50 cm globe was used and fibreglass continents prepared with great circle distances from the same central point increased by a factor of  $0.75^{-1} = 1.33$  above the present.

A grouping of continents transitional between the primeval grouping (Figs. 1a and 2a) and the grouping in

Pangaea (Fig. 1c) was easily obtained and is illustrated in Figs. 1b and 2b. Thus, if the Earth has expanded, it appears to have done so in such a way that the sialic skin first developed a U-shaped crack between Australia and America and between Australia and Asia. Subsequent expansion then appears to have been taken up largely in this initial crack, which widened to form the Pacific Basin.

As the slow expansion proceeded, the sialic skin would have to adjust itself to the decreasing curvature and the various parts of Pangaea would experience considerable changes in latitude and longitude. This might be considered as a kind of continental drift but of completely different origin and nature from that of the more rapid and familiar kind to which palaeomagnetic evidence relates and which occurred during the past few hundred million years.

#### Distortion produced on Change of Curvature

The amount of distortion in shape produced by the radial expansion method depends on the great circle distance of an element of coastline from the centre of expansion. Let us consider how a circular spherical cap subtending a semi-angle  $\theta$  at the centre of the sphere might adjust itself to the decreasing curvature of an expanding sphere while maintaining a constant surface area. Circular elements of area could expand or contract by an amount depending on the angle subtended with

Table 2a. SEMI-ANGLES SUBTENDED BY CONTINENTS

Continent	Maximum	Minimum
South America	35°	10°
Africa	40°	10°
Australia	20°	10°
Europe	20°	10°
Asia	45°	20°
North America	30°	15°
India	10°	5°
Antarctica	20°	10°
Pangaea	90°-100°	10°-20°

TABLE 2b. SPHERICAL CAP OF CONSTANT AREA ON AN EXPANDING GLOBE

Semi-angle subtended by circular spherical cap on a globe of		Ratio of circumferences (2)/(1)
(1) Radius $R$	(2) Radius $2R$	
45°	22°	1.08
60°	29°	1.16
70°	33°	1.19
80°	37°	1.22
100°	45°	1.43
118°	50°	1.71
135°	55°	2.32
180°	90°	∞

the centre. The semi-angle  $\theta'$  subtended on the larger sphere is related to  $\theta$  by  $2\pi R^2(1 - \cos \theta) = 2\pi R'^2(1 - \cos \theta')$ . However, the length of the circumference must change because the new circumference  $2\pi R' \sin \theta'$  is different from the old unless  $\sin \theta = \theta$ , which is certainly not true for angles subtended by the continents (Table 2a).

Factors by which the circumference increases for different initial and final angles  $\theta$  and  $\theta'$  are given in Table 2b. Since the various parts of the coastlines of continents subtend different angles  $\theta$  from the respective chosen centres of expansion, the shape of continents deduced for the smaller Earth using the model will differ in some measure from their present shapes.

The model of expansion used supposes that the shell of continental material adjusted itself to the new curvature by plastic flow. However, if the continents developed from a spherical shell on an expanding Earth, the shell would presumably have cracked. For a large number of very small cracks the result would be that for plastic flow, for the cracks would have been filled in by continental material transported from regions near the centre, where crustal thickening and hence uplift would have occurred.

However, as pointed out in the previous section, a large U-shaped crack seems to have developed round what is now the Pacific Basin. A subsidiary crack also appears

to have developed along the line of the Tethys Basin. If afterwards, smaller cracks formed, adjustments in curvature may possibly have developed in independent units of fairly small  $\theta$  of about the same size as the present continents. Thus the distortion produced by the radial expansion method need not be very different from that which could have occurred if the continents have developed on an expanding Earth. For large values of  $\theta$  such as we would have to consider if we tried to adjust the whole of Pangaea to the greater curvature of an initially smaller Earth the distortion would be impossibly great (Table 2). For values of  $\theta$  typical of the present continents, however, the distortion may at worst be about 20 per cent, this being the difference between the columns in Table 2, that is, for maximum and minimum  $\theta$  for each continent. Redistribution of continental material within Pangaea during most of its history before it broke up is irrelevant to the problem of fit, because the Earth had grown almost to its present size before disintegration commenced.

### Supercontinental Drift

In the Devonian and for the remainder of the Palaeozoic there is varied evidence that two supercontinents, Laurasia and Gondwanaland, existed<sup>4,5</sup>. The reconstruction based on palaeomagnetic data is illustrated in Fig. 3.

It thus appears possible that a phase of continental drift occurred in pre-Devonian times when Pangaea broke into two parts, Laurasia and Gondwanaland, which afterwards drifted apart, leaving the Tethys Sea between them. Palaeomagnetic data for the lower Palaeozoic and the late Pre-Cambrian are insufficient at present to deduce when this predicted 'supercontinental' drift occurred.

### Rate of Expansion

The expansion hypothesis provides a possible explanation for the development of Pangaea, the periphery of which is so shaped that it could conceivably have covered the entire surface of a smaller Earth. However, the fit of the edges of the continents which comprised Gondwanaland is better for an Earth of the present size than for the smaller Earths, as can be seen by comparing Figs. 1a, b and c. Everitt<sup>12</sup>, who has recently used an electronic

Fig. 3. Reconstruction for the Devonian deduced from palaeomagnetic data on present-size Earth. The polar paths for the Upper Palaeozoic and subsequent geological time are numbered as follows: (1) South America, (2) Africa, (3) Australia, (4) Europe and West Russia, (5) North America, (6) India, and (7) Antarctica. Curve 5 diverges from the main curve in the Pennsylvanian, Curve 4 in the Permian and curves 1, 2, 3, 6 and 7 diverge in the Upper Permian or Triassic

Fig. 4a, b and c. Earth expansion according to following laws: (1)  $R = R_0 (1 + at)$ , (2)  $V = V_0 \exp \beta t$ , and (3)  $V = V_0 (1 + \gamma t)$ . The shaded part corresponds to Phanerozoic time

computer to adjust the continents into their best-fitting positions, has drawn maps which exhibit an almost perfect fit of: (1) South America and Africa; (2) North America, Greenland and Western Europe. These fits could certainly not be bettered by recomputation for a smaller Earth. The fit of Australia and Antarctica into the Pacific is not so good for shell models of the present Earth and appears rather better for a smaller Earth.

Thus it can be argued that the Earth's radius was not appreciably different from its present value when the fragmentation of Laurasia and Gondwanaland commenced<sup>4,5</sup> in the Permian or Triassic. This conclusion is supported by the palaeomagnetic evidence given in Table 1. Van Hilten<sup>10</sup>, who, alone among those who have considered the palaeomagnetic data, argues that the Permian radius was appreciably less than the present, has on this basis deduced a rather strange reconstruction of the continents for the Permian. I think his conclusions are wrong since the Permian palaeomagnetic data are consistent with du Toit's reconstruction<sup>4,5</sup> on an Earth of the present radius. Hence a rapid and recent Earth expansion as advocated by Carey<sup>1</sup> appears most improbable.

Let us now suppose that the expansion has been occurring throughout the Earth's life and hence try to draw some conclusions about possible present rates of expansion. In an Earth formed by the accretion of cold bodies, radioactive heating would enable chemical evolution to take place fairly quickly. It has been estimated<sup>13</sup> that a proto-core would form in about 500 million years.

The process of chemical evolution might have been approaching completion after about 1,000 million years, although it may still be happening on a small scale even to-day. Thus, the sialic continental material may have entirely covered the Earth when it was about 1,000 million years old. Its radius would then have been about 0.55 times its present value. The Earth is now thought to be about 4,500 million years old.

In the absence of an explanation of the supposed expansion let us consider three simple laws: (1)  $R = R_0 (1 + at)$ , a steady increase of radius with time; (2)  $V = V_0 \exp \beta t$ , in which the incremental increase in volume at any time is proportional to the volume at that time; (3)  $V = V_0 (1 + \gamma t)$ , a steady increase in volume with time. These laws are illustrated in Figs. 4a, b and c, from which we see that (1) and (2) are nearly identical. If we consider law (3) we find that  $V_0$  would have to be negative if  $R = 0.55 R$  (present) at  $t = 10^9$  years and  $V_0$  would equal 0 at  $t = 0$  if  $R$  had the foregoing value at  $t = 0.74 \times 10^9$  years. In Table 3, Earth radii, surface areas and volumes are given for all three cases for 200 million years ago (Permo-Triassic) and 500 million years ago (lower Palaeozoic).

Table 3

Expansion law	Radius (km)	
	200 m.y. ago	500 m.y. ago
$R = R_0 (1 + at)$	6,205 (2.6%)	5,960 (6.4%)
$V = V_0 \exp \beta t$	6,180 (3.0%)	5,840 (8.0%)
$V = V_0 (1 + \gamma t)$	6,270 (1.6%)	6,110 (4.1%)
(Present radius 6,370 km)		
	Surface area ( $10^6 \text{ km}^2$ )	
	200 m.y. ago	500 m.y. ago
$R = R_0 (1 + at)$	485 (4.9%)	448 (12.6%)
$V = V_0 \exp \beta t$	476 (6.6%)	430 (15.8%)
$V = V_0 (1 + \gamma t)$	497 (2.5%)	474 (7.1%)
(Present surface area $510 \times 10^6 \text{ km}^2$ )		
	Volume ( $10^6 \text{ km}^3$ )	
	200 m.y. ago	500 m.y. ago
$R = R_0 (1 + at)$	1.02 (5.6%)	0.90 (16.7%)
$V = V_0 \exp \beta t$	0.98 (9.3%)	0.83 (23.2%)
$V = V_0 (1 + \gamma t)$	1.03 (4.6%)	0.96 (11.1%)
(Present volume $1.08 \times 10^6 \text{ km}^3$ )		

Expansions in percentages of present values are given in brackets.

### Earth Expansion, Continental Drift and Mountain Building

In Table 4, typical times which might be associated with each of the foregoing processes are listed. Because of the comparatively long typical time associated with Earth expansion, I think it unreasonable to invoke it as the principal cause or source of energy for drift or orogeny. Even so, a few geologists have recently attempted<sup>1,14</sup> to do this. I think that expansion should be regarded as something which may have been gently, but persistently, occurring in the background. There may be little obvious geological evidence of expansion: most of this could easily have been obscured by more vicious and rapid processes such as continental drift and orogeny.

Table 4

Phenomenon	Typical time ( $10^9$ years)	Presumed source of energy
Earth expansion	Time for earth radius to increase by a factor $e$	4,000-5,000 Cosmological
Polar wandering	Time for $180^\circ$ of polar wander at the observed rate of $2/3^\circ$ per million years	250 Planetary
Continental drift	Duration of a phase of drift—approx. one geological era (for example, Mesozoic)	200 Planetary (in mantle)
Orogenesis	Duration of Alpine orogeny	20 Regional (in crust and upper mantle)

If Pangaea developed along the lines described, two questions arise. First, why did continental drift not occur until such a late stage in the Earth's development; and secondly, why was its shape not distorted out of all recognition by mountain building processes and erosion?

On this hypothesis of development, the first phase of continental drift occurred before the Devonian when Pangaea bisected to form Laurasia and Gondwanaland. The second and main phase occurred during the Mesozoic. It is noted that some geologists have pointed out that orogenic activity has slowly increased in frequency during geological time, that is, the period for which there is a continuous geological record. Thus, orogenic activity, and hence erosion, may have played a much smaller part in the development of the crust in the remote past than is indicated by geological evidence for recent periods. This possibly explains why it appears that sections of the edge of Pangaea retained their initial shapes so well.

It may well be a long time before sufficient evidence pertinent to the expansion hypothesis is found. Careful investigations of Pre-Cambrian rocks should yield useful results. Geological examinations on other Earth type planets may be revealing, particularly if one is found where neither orogenic activity nor mantle convection has occurred. For an adequate explanation we may well have to await a satisfactory theory of the origin and

development of the universe<sup>16</sup>. In the meantime, we should beware of rejecting the hypothesis of expansion out of hand on grounds that no known sources of energy are adequate. It may be fundamentally wrong to attempt to extrapolate the laws of physics as we know them to-day to times of the order of the age of the Earth and of the universe.

## DERMATOGLYPHIC TOPOLOGY

By PROF. L. S. PENROSE, F.R.S.

Galton Laboratory, University College, London

THE ridges which form the dermatoglyphic patterns on the ventral surfaces of the hands and feet are arranged in lines which are parallel in small fields. Two kinds of discontinuity of pattern are found; these occur at the centres of what are termed loops and triradii. Around the core of a loop (Fig. 1) the direction of the ridges turns through an angle of 180°. The centre of a triradius (Fig. 2) is the point where three different fields of almost parallel ridges meet. The result produces three spokes; the angles between them are greater than 90° and are typically each 120°.

On the fingers and toes a single loop is accompanied by one triradius (see Fig. 3). When two loops are present there are two triradii, and the same applies to a symmetrical whorl in which two loops have become fused.

Fig. 1. Loop pattern

Fig. 2. Triradius

Fig. 3. Configurations on digits; (i) arch, (ii) loop, (iii) whorl

Fig. 4. Minimal number of triradii on hand

Fig. 5. Left hand with multiple ridge patterns

Curvature of the lines which is insufficient to make a loop is called an arch.

On the palms the minimal number of triradii is four. These are usually in the positions designated *a*, *b*, *d* and *t* (see Fig. 4). For every loop which occurs on the palm there is another triradius. Moreover, it can be shown empirically that, over the whole hand, including the fingers, the number of triradii exceeds the number of

loops by four. In Fig. 5 the hand has 18 triradii and 14 loops. The explanation for this is that, at the junction between the ridged skin on the palmar surface and the thinner skin on the dorsal surface, the ridges run at right angles to the axis of the limb.

An exceptional arrangement occurs at the apex of each digit, where the ridges lie nearly parallel to the edge of the nail; this is equivalent to the presence of a loop pattern the core of which is replaced by part of the nail. The wrist is also exceptional and, again, it corresponds topologically to a loop. Indeed, the whole ridged surface of the hand can be mapped on a circle (see Fig. 6) in which all ridges meet the circumference at right angles. Provided that such an area is covered with ridges parallel to one another in small fields, it is topologically necessary that at least two loops are present somewhere on it (see Fig. 7). For every additional loop (see Fig. 8) there must be a compensating triradius. Thus, the total number of

Fig. 6. Circular topological diagram of the hand shown in Fig. 4

Fig. 7. Circular area with ridges meeting circumference at right angles; two loops are essential

Fig. 8. Circular area as in Fig. 7, but with three loops and one triradius

Fig. 9. Examples of palmar dermatoglyphics on malformed right hands with 6, 4, 3, 2 and 1 digits, respectively. (i) Hexadactyly in 13-15 trisomy,  $13+1=8+6$ . (ii) Hereditary ectronychia,  $7+1=4+4$ . (iii) Sporadic deformity,  $6+1=4+3$ . (iv) Hereditary ectrodactyly,  $9+1=8+2$ . (v) Hereditary ectrodactyly,  $3+1=3+1$ .

Fig. 10. Indistinct triradius on ulnar edge of the palm

Fig. 11. Diagram of ridges on terminal phalanx of normal thumb which shows a loop vestige near the apex

Fig. 12. Diagram of ridges on terminal phalanx of anonychie thumb on which there are four loops but only two triradii

loops will always be two more than the total number of triradii.

Returning to consideration of the hand, remembering that each digit is equivalent to one loop and leaving out the wrist, a general dermatoglyphic formula is obtained. Thus, if  $T$  is the number of triradii,  $L$  the number of loops and  $D$  the number of digits,

$$T + 1 = L + D$$

Had the wrist been included, a unit would have been added to each side of the equation. Obviously, in the normal hand where  $D = 5$ ,  $T - L = 4$ , as already observed. Normal feet are governed by the same formula, but the complete dermatoglyphic configuration is much less easily identified on soles than on palms. The triradii at the bases of the toes are often extremely difficult to find. The rule can be tested by analysing hands with malformations which have deprived them of digits or increased their number. In all examples shown (Fig. 9) the formula is correct.

There are three kinds of conditions which can invalidate the rule. The first type is trivial but common. This is that a triradius or loop fails to be observed on a print although it is actually present. Reference to the equation sometimes shows that the pattern has been incorrectly recorded.

The second source of deviation is that part of a pattern may be so close to the edge, beyond which the ridged skin does not extend, that it may have been incompletely formed. For example, a triradius on the extreme ulnar aspect of the palm, though topologically necessary, may nevertheless be scarcely visible (Fig. 10).

The third origin of exceptions is of critical interest. It concerns the apices of the fingers. On the thumb especially, the ridges do not lie exactly parallel to the hyponychium, and in normal hands occasionally a small loop is actually present towards the ulnar side (Fig. 11). In abnormal circumstances, when the nail is diminished or absent, as in anonychia, the dermal ridges may extend over the area normally covered by the nail. In such instances, as might be expected on topological grounds, there are two loops without accompanying triradii (Fig. 12). The reason for this pattern is that the ridges have trespassed on to the dorsal surface of the hand, where the same rules apply independently as on the palmar surface. The presence of the normal nail indeed is a substitute for two loops, and, from the topological point of view, one belongs to the dorsal and the other to the ventral surface of the digit.

The topological analysis of dermal ridges, besides leading to searches for new configurations, may throw

light on the developmental background. The fact that the ridges run predominantly at right angles to the long axes of the limbs and the digits suggests that they take the shortest courses possible. The symmetrical form of most triradii, with angles of nearly  $120^\circ$ , is also compatible with this view. Observations on the ridge formations on palms and soles of both New World and Old World monkeys indicate that whorls occur on the volar pads<sup>1</sup>. In the human fetus the pattern of ridges is determined at an early stage in the development of the limb when the proportional sizes of digits and pads are different from those in the adult. The permanent configuration is the result of laying a carpet of parallel lines, in some way as economically as possible, over the contours presented by the foetal hand.

I thank Mr. A. J. Lee for assistance in preparing the figures.

## NEWS and VIEWS

### The Council for National Academic Awards

H.R.H. PRINCE PHILIP, Duke of Edinburgh, has accepted an invitation to be president of the Council for National Academic Awards. The Council for National Academic Awards is an autonomous body which was established by Royal Charter in September 1964, with powers to award degrees, diplomas, certificates and other academic awards to persons who have successfully pursued courses of study approved by the Council at educational establishments other than universities or who have successfully carried out research work under the supervision of an educational or research establishment other than a university. The Council will award degrees and other academic distinctions, comparable in standard with awards granted and conferred by universities, to students who pursue their higher education in establishments for further education which do not have the power to award their own degrees. The Council will deal with Scottish colleges as well as colleges in England and Wales. Sir Harold Roxbee Cox is chairman of the Council (see *Nature*, 201, 975; 1964).

### The Geological Society of London:

#### Awards

THE following awards for 1964 have been made by the Geological Society of London: *Wollaston Medal*, to Prof. D. M. S. Watson, emeritus professor of zoology and comparative anatomy, University College, London, for his distinguished researches in the field of vertebrate palaeontology; *Murchison Medal*, to Prof. W. F. Whittard, Channing Wills professor of geology, University of Bristol, in recognition of his researches on the stratigraphy and palaeontology of the Silurian and his direction of marine geological investigations; *Lyell Medal*, to Prof. C. F. Davidson, University of St. Andrews, for his petrological work on the rocks of the Hebrides and his mineralogical and economic researches on atomic minerals; *Bigsby Medal*, to Prof. J. Sutton and Dr. Janet Watson (Mrs. J. Sutton), Department of Geology, Imperial College of Science and Technology, for their fundamental contributions to the stratigraphy, structure and metamorphism of the Scottish Highlands; *Wollaston Fund*, to Dr. H. W. Ball, Department of Palaeontology, British Museum (Natural History), for his stratigraphical and palaeontological researches, especially on the Old Red Sandstone and fossil fish; *Murchison Fund*, to Dr. I. Strachan, lecturer, Department of Geology, University of Birmingham, for his work on graptolites and Pleistocene palynology; *Lyell Fund*, a moiety to Mr. S. W. Hester, Geological Survey and Museum, London, for his palaeontological and stratigraphical work on the Upper Carbon-

iferous, and another moiety to Mr. R. Stoneley, geologist, British Petroleum Development, Ltd., in recognition of his work in Antarctica, and for stratigraphical and structural studies in East Africa, New Zealand and Alaska in connexion with exploration for petroleum.

### Biology in the Massachusetts Institute of Technology:

#### Dr. S. E. Luria

IN recognition of the work in bacteriology and public health of the late Dr. W. T. Sedgwick, the William Thompson Sedgwick professorship in biology has been established by the Massachusetts Institute of Technology. Dr. S. E. Luria has been named as the first Sedgwick professor. Dr. Luria received his medical degree at the University of Turin in 1935. He pursued his research in microbiology at the Institute of Radium, Paris, and at various universities in the United States before joining the faculty of the Massachusetts Institute of Technology in 1958, where he established a new programme of microbiological research and teaching within the Department of Biology. Dr. Luria is probably best known for his research on the genetics of bacteria and on the genetic influences exerted by viruses over the bacterial cells they invade. He is the author of more than one hundred technical papers.

### Ministry of Technology

IN a written answer in the House of Commons on January 21 the Prime Minister stated that the branch of the Department of Education and Science concerned with policy for nuclear energy, and a small section of the Ministry of Aviation responsible for sponsoring the electronics industry, had been incorporated within the Ministry of Technology. The greater part of the existing headquarters of the Department of Scientific and Industrial Research, together with most of its stations, and the branch of the Board of Trade concerned with policy for the National Research Development Corporation would also be transferred to the Ministry of Technology when the necessary legislation and Statutory Instrument took effect. In all, rather more than 5,000 staff, including industrial workers, were involved.

### Manpower Resources for Science and Technology

IN answer to a question in the House of Commons on January 21, the then Secretary of State for Education and Science, Mr. M. Stewart, said that a new survey of scientific manpower was now being undertaken. The results of this would probably be available by about the middle of this year and could then be interpreted by the new Committee on Manpower Resources for Science and Technology. In a written answer, also on January 21,

Mr. Stewart added that he expected that the target of 20,000 graduates a year in pure or applied science set for about 1970 by the Barlow Committee would be met during 1965. Rather more than 25,000 boys and girls left school in the year 1962-63 with two or more passes in the Advanced Level Examination for the General Certificate of Education, at least one of which, and mostly all of which, were in science subjects.

### Land and Natural Resources

IN a written answer in the House of Commons on January 19, the Prime Minister stated that the Minister of Land and Natural Resources would be responsible for research into the possibilities of conserving and augmenting national water resources. Accordingly, the new Minister would assume responsibility for those aspects of the Minister of Housing and Local Government's work concerned with the Water Resources Board, including the appointment of members and financial responsibility. He would take a leading part in any major projects, such as estuarial barrages, which involve co-ordination of various different interests in a particular river and with which a number of different Departments are concerned. He would also be responsible for plans for reorganizing the water supply industry under full public ownership. However, the Minister of Housing and Local Government would continue in England to exercise his statutory functions in relation to water supply and river management, particularly executive responsibility for questions of water distribution, minimum acceptable flow in rivers, abstractions, river pollution and sewerage. He would also share with the Secretary of State for Wales his existing statutory responsibilities for the appointment and functioning of river authorities, but the Minister of Land and Natural Resources would also be one of the Ministers who appoint those members of river authorities who are "qualified in respect of public water supply". Appropriate arrangements would be made between the three Ministers about future appointments to the three river authorities concerned with catchment areas in both England and Wales, and these authorities would look to London or Cardiff as appropriate for the problem. The provisions of the Water Resources Act, 1963, were not as yet fully in effect and the position would be kept under review to see whether experience in implementing those provisions called for any change in these arrangements. The position in Scotland was unchanged. In a further answer on January 21 the Prime Minister added that details of the Minister's responsibilities for the establishment of a Land Commission and for future policy relating to the availability of land would be set out in a Transfer of Functions Order to be laid before the House.

### Scientific Advisory Panel to the Ministry of Agriculture, Fisheries and Food

IN a written reply to a question in the House of Commons on January 21 concerning arrangements for securing advice on the scientific aspects of questions arising within the field of agriculture, fisheries and food, Mr. F. Peart, Minister of Agriculture, Fisheries and Food, said that he had gone into this question following the retirement of Sir Harold Sanders from the post of chief scientific adviser (agriculture), and had decided to establish a Scientific Advisory Panel under the chairmanship of Prof. A. C. Frazer, of the University of Birmingham. This Panel would be available to advise him on the scientific aspects of any questions affecting the activities of his Department which might be referred to it. The Panel would also be free to offer its advice on any problems in this field whenever in its view this was desirable. The responsibilities of the heads of the scientific branches in the Ministry would not be affected in any way by these new arrangements. On the other hand, it was hoped that the establishment of the Panel would lead to closer links between the universities and the Ministry.

### The World Weather Centre, Washington

THE World Weather Centre in Washington commenced operation on January 1 and is now providing services on request to all members of the World Meteorological Organization. Essentially it is concerned with gathering, processing and distributing weather observations. It will prepare weather analyses and forecasts for as much of the globe as possible. From the Centre, the processed weather information will be transmitted to regional and national meteorological centres. Opportunities will be provided for training meteorologists from member countries. The Centre will conduct both basic and applied research on large-scale weather problems, and will store weather information for research purposes. The planned activities of the Centre cannot as yet be fully implemented because weather data are not available over much of the Earth's oceanic areas. Moreover, the present meteorological satellite system does not as yet provide global satellite coverage. However, it is hoped that the *Tiros* Operational Satellite System, which is planned to be launched in about a year's time, will eliminate that deficiency. Plans are being developed to implement the Centre in progressive steps. The events leading to the establishment of the World Meteorological Centre began in 1960, when the first two *Tiros* weather satellites were successfully launched. Photographs taken by television cameras on board were used by the U.S. Department of Commerce Weather Bureau in improving analyses, forecasts and warnings. Washington and Moscow have already been designated as World Centres by the World Meteorological Organization, and a third centre in the southern hemisphere is envisaged.

### Annual Growth Rate in Britain

IN the *Westminster Bank Review* for November 1964, an article by Prof. Alan Day, "The Myth of Four Per Cent Growth", estimates the present annual growth of capacity as 3.3 per cent, to which may be added an extra 0.2 per cent to be activated by a regional policy designed to make use of under-employed labour in the North. This suggests that, while the latter policy could also lead to greater inflationary pressures, since the upward trend in the ratio of rate of investment to gross national product appears to have levelled out since 1961, the annual rise of productivity may become stabilized at about 2.7 per cent. Prof. Day also expects a slower rise in the labour force, but nevertheless believes we could achieve a 4 per cent growth, including a big increase in the ratio of investment to national income, though at the price of a severe but temporary setback to the growth of present expenditure. Four per cent could serve a useful social purpose if treated as a target to be achieved only by sacrificing present consumption and severe disturbance to vested interests and economic and social rigidities.

### Careers in Biology

SINCE the first edition of *Biology as a Career* appeared in 1953, there has been a steady expansion of biological science and a perceptibly growing recognition by the public of its value. The fourth edition is published under the conviction that there is now greater need than ever for a general guide describing the training, work and prospects of the professional biologist (Pp. 44. London: Institute of Biology, 1964. 3s. 6d.). In this booklet, the opportunity has been taken to bring facts up to date and to include a new appendix, indicating qualifications necessary for entry as well as giving brief details of the interests of the biological departments of British universities.

### Kindrogan Field Centre

THE Scottish Field Studies Association Field Centre in Garth Memorial Hostel was closed at the end of 1963 and a new, self-contained, residential field centre was opened in March 1964 at Kindrogan, a large country house stand-

ing in 10 acres of ground in Strathardle, Perthshire (The Scottish Field Studies Association. Annual Report, 1963. Edited by B. W. Ribbons. Pp. 27 + 4 plates. Glasgow: The Scottish Field Studies Association, 1964. 4s.). This new permanent field centre affords excellent opportunities for work in the Scottish Highlands on biology, physical geology, physical and human geography and archaeology. Close to the centre are coniferous and deciduous woodland, freshwater river, loch and lochan, dry and wet moorland, glacial moraines, terraces and haughs, and the remains of a small highland village. The Highland Boundary Fault is at hand and a few miles away are Ben Vrackie, Glen Shee, Glen Isla, Beinn A'Ghlo and Killiecrankie. Kindrogan stands at an altitude of 850 feet, and has an annual rainfall of 38 inches. Amateur naturalists and research workers are invited to use the centre for their own private work and to join courses organized by the Association, together with groups of pupils and students accompanied or unaccompanied by their own staff. The standard of such courses is adjusted to suit the needs of those present, and the Association is also prepared to consider arranging courses to suit particular groups. Details of the courses and facilities available may be obtained from the Warden, Kindrogan Field Centre, Enochdhu, Blairgowrie, Perthshire.

### The Quaker Approach to Life

IN her eighteenth Eddington Memorial Lecture, now published, Dr. K. Lonsdale gives a moving and sincere account of the development of her faith as a part of her whole experience of and outlook on life (*I Believe* . . . Pp. 56. Cambridge: at the University Press, 1964. 4s. 6d.). This attitude to life as an experiment calling for commitment, as Dr. J. H. Oldham did, brings out the essential harmony between her work and her faith. Religious truth, she argues, is known to us through religious experience, that of ourselves and of others, and includes scientific experience, while going far beyond it. Even to those who may not follow her on some particular points Dr. Lonsdale's lecture makes refreshing reading and a stimulating challenge to approach life as a whole, much in the spirit of Donald Hankey half a century ago.

### The National Institute of Sciences of India

THE Yearbook of the National Institute of Sciences of India, 1963, constitutes the usual reference work with lists of Fellows, Council and senior office staff, membership of committees, rules and regulations, medals and lecturers, and publications (Pp. vi + 241. New Delhi: National Institute of Sciences of India, 1964. 15 Rs.). The Council's report summarizes the anniversary address of the President, Dr. A. N. Khosla, and gives particulars of the symposia, on endocrinology of reproduction, vitamin metabolism, and fertility of Indian soils, arranged during the year. Proposals are under consideration for development of the Institute on the lines of the Royal Society, and steps are being taken to expedite publication of scientific papers, including removal of the Publications Office from Calcutta to Delhi. Brief reports on researches in mathematics, physics, chemistry and physiology are appended.

### Science and Technology in Poland

THE tentative analysis of the present state of Polish science contributed by H. Jablenski to the *Review of the Polish Academy of Sciences* for April-June 1964 (9, No. 2; 1964) considers successively the position of the biological sciences, medical studies, chemical sciences, mathematical and physical sciences, geology and technical sciences in Poland in relation to the extent to which they meet the needs of Poland, the relations between the several disciplines and gaps which should be filled. The same issue also contains the abridged text of an address by the Deputy Prime Minister, E. Szyr, on the responsibilities, organization and methods of work of the Committee on Science and Technology.

### Roumanian Scientific Abstracts

THE Scientific Documentation Centre of the Academy of the Roumanian People's Republic is now issuing monthly: *Roumanian Scientific Abstracts*. These are to be published in two series, on natural sciences and social sciences, from January/February 1964, in English and Russian, and will provide scientists abroad with complete and rapid information on Roumanian research in these fields. In the issue for the natural sciences, entries are arranged under mathematics and astronomy, physics, chemistry, and biology. Nineteen periodicals are covered.

### New Zealand Department of Scientific and Industrial Research

THE New Zealand *D.S.I.R. Handbook 1964*, which supersedes the 1960 edition, contains in general information compiled by the staff of the Department's Information Service up to March 31, 1964, but since organization and administration of science in New Zealand are at present undergoing important changes some gaps in the coverage are inevitable (Pp. 104. Wellington: Government Printer, 1964). Besides outlining the general organization of the Department, the *Handbook* gives, for each Division or institution, the address, principal officers and an outline of the scope of its work.

### Building Material Properties Classified

ARCHITECTS and builders require a good deal of detailed technical and economic information to permit choice between a number of possible materials or products. For this information reliance is often on technical literature supplied by manufacturers, sometimes supplemented by results of tests or assessments made by independent test houses or research organizations, or on documentation available from building information centres. There is at present no established system for presenting this sort of information, such as could facilitate comparison of similar products on the basis of essential relevant properties of materials and products. To meet this need a report has been prepared, entitled *A Master List of Properties for Building Materials and Products* (CIB Report No. 3. Prepared by CIB Working Commission W. 31. Pp. 20. Rotterdam: General Secretariat, CIB, P.O. Box 299, 1964. 2 Sw. francs). This is an important step towards uniformity of presentation and a systematic framework for setting out values for physical properties and design data without actually specifying any particular standards. Under the heading 'Properties', this *Master List* gives guidance on general information; composition and method of manufacture; shape, dimensions, weight; general appearance; physical, chemical and biological properties; durability; special technical properties for installations, mechanical plant, equipment, etc.; working characteristics; and functional properties of common types of building elements in which the material or product is incorporated. Under the heading 'design considerations and details: suitable applications', there are included architectural and constructional details; examples of common mistakes in design and work; and references. Instructions for work and maintenance embrace this subject, site testing and instructions for cleaning and maintenance. Other headings are economics; specification of distribution; sales organization; contract work; technical service. "Because it is intended to be comprehensive, not every property in the list will apply to every product, and the Working Commission (W 31) is going to produce separate lists, based on this master list, that will relate to various classes of materials or products and to materials or products used for particular purposes." This is a most useful summary of data essential to modern building practice and should be in the hands of all concerned with building construction where only the best will satisfy.

## National Soil Survey of Ireland

A SYSTEMATIC soil survey of Ireland has been undertaken by the Agricultural Institute, and Bulletin No. 1 is an account of the *Soils of Co. Wexford*, by M. J. Gardiner and Pierce Ryan (Pp. 171+xiii. 31 Plates. 3 Maps. Foras Taluntais: 33 Merrion Road, Dublin 4, 1964. 30s.). Apart from the Leinster Mountains, which rise to 2,610 ft. in the north-west, most of the county consists of gently undulating country below 750 ft. with a relatively favourable maritime climate, the average rainfall varying from 34 in. on the coast to 48 in. near the mountains, the average monthly temperature from 40° to 60° F and the relative humidity from 70 to 80 per cent. The solid geology consists mainly of granite and mica-schist in the higher ground, Ordovician shale associated with volcanic rocks in the central region, and Cambrian shale with a belt of Carboniferous limestone in the low-lying area. But most of the County is covered by glacial deposits of different ages and most of the soils have been derived from the Saale glaciation and form a complex pattern. A chapter of 50 pages is given to a full description of the soil associations and series, including regosols, brown earths, podzols, gleys, lithosols and organic soils, and their classification into the Great Soil Groups. There are discussions of analytical data in relation to the main soil associations and of the suitability of the various soils for the usual range of crops, including pasture and forest, concluding with a suitability classification. A chapter on the agricultural pattern is contributed by M. T. Connolly. The three maps, on the scale 2 miles to 1 in., describe the soils, the soil drainage and the soil suitability.

## Measuring Techniques in Coastal Waters

A PAPER in the *South African Journal of Science* (60, No. 9; September 1964), by C. C. Stacopoulos, describes the classical methods of measuring temperature, salinity and ocean currents, and discusses their limitations in coastal waters. Preference is given to techniques which give rapid coverage in space and time, rather than to those which give a precision which may not be justified in near-shore water. Electrical salinometry and electrical thermometry in various forms have proved the most useful. A method of measuring near-surface currents up to distances of 3 miles offshore is recorded, as well as a rapid method of measuring currents at numerous depths in profile and to greater distances offshore. Time series current measurements have been obtained from observations on a system of buoys offshore.

## Cardiac Pacemakers

VOLUME 3, Article 3 of *Annals of the New York Academy of Sciences* presents the papers and records the discussion that took place from them at a conference held under the chairmanship of Dr. W. W. L. Glenn, and sponsored jointly by the New York Academy of Sciences and the Council of Cardiovascular Surgery of the American Heart Association (*Cardiac Pacemakers*. Pp. 813-1122. New York: New York Academy of Sciences, 1964. 7 dollars). Twenty-five papers are presented. They range from reviews of the normal anatomy and clinical aspects of the conduction system of the heart in man to its abnormal behaviour in disease leading to the need for artificial cardiac pacemaking. Papers cover the full range of present knowledge on the means available for artificial pacemaking. Conventional non-synchronous electrical pacemakers now support an increasing population of patients in active life, who were previously condemned to sudden loss of consciousness and the risk of death from cardiac standstill. The techniques used for this treatment are reviewed in detail and the disadvantages of these methods are clearly stated. Numerous papers on the experimental approach to more effective methods are also presented in this volume. They give an exciting glimpse

of technical, pharmacological and physiological advances in this field which will yield both an increase in benefits to patients and new knowledge of the biochemical and physiological behaviour of the heart itself. This volume should be looked on as essential reading for the clinician and clinical research worker in this field. There is one surprising omission to be found in this very complete symposium. The cardiologist required to provide a medical and technical service for artificial electrical pacemaking of the heart would have valued an article giving special guidance on the medical and technical hazards and requirements needed to provide an efficient testing and maintenance service for these devices once they have been installed in the patient's body. The patient's life depends on the efficiency and the reliability of these devices. These in turn depend on the efficiency of the medical and technical organization for installation, maintenance, servicing and replacement of procedures within the patient's body when the need arises.

## The Paul Instrument Fund Awards

THE Paul Instrument Fund Committee has made grants as follows: £3,500 to Dr. J. E. Baldwin, assistant director of research in the Cavendish Laboratory, Cambridge, for the construction of a receiver for measuring power spectrum of a radio-frequency noise source using auto-correlation techniques in a large number of parallel channels. £7,800 to Dr. R. D. Davies, senior lecturer in radio astronomy, University of Manchester, for the construction of a spectrometer for radio astronomy using digital auto-correlation techniques with a sampling switch rate of 4 Mc/s, which it is hoped can be increased to 10 Mc/s and even to 100 Mc/s. £2,700 per annum for three years to Prof. J. D. McGee, professor of applied physics, Imperial College of Science and Technology, London, for the development of a photoelectronic image device for time resolution of rapidly changing optical images. £3,000 to Dr. D. W. Turner, lecturer in organic chemistry, Imperial College of Science and Technology, London, for the development of high-resolution electron spectrometry techniques, which are to be joined with the new molecular photoelectron spectroscopy approach to higher ionization potential determination: two spectrometers are envisaged, for the study of molecular *L* shells and *K* shell electrons, respectively. The Paul Instrument Fund Committee, composed of representatives of the Royal Society, the Institute of Physics and the Physical Society, and the Institution of Electrical Engineers, was set up in 1945 "to receive applications from British subjects who are research workers in Great Britain for grants for the design, construction and maintenance of novel, unusual or much-improved types of physical instruments and apparatus for investigations in pure or applied physical science".

## Nuffield Foundation Scholarships and Bursaries

THE Nuffield Foundation is offering a number of biological awards, scholarships and bursaries to scientists who wish to receive training in other fields of science. Until 1963, graduates in biology were not eligible for these awards, the purpose of which was to encourage graduates in the physical sciences to make a complete change by receiving training in biology. It was then decided that the conditions should be extended to assist graduates in biological subjects to study appropriate aspects of mathematics, physics or chemistry. The purpose of the enlarged scheme remains the same: to encourage progress in the many branches of botany and zoology, which is at present blocked for lack of workers who have an adequate grasp of the physical sciences, and to break away from the traditional descriptive form of teaching. In the case of candidates making the change to biology, awards are made for nothing less than a training in a fairly wide, selected field of biological subjects, and it must always be the candidate's intention to make his future career in biology. It is in the desire to

turn to biology and to apply in it the knowledge and methods of the physical sciences that success for the scheme and progress in biology will lie. This needs to be emphasized; experience has shown that graduates and even their sponsoring professors have sometimes failed to understand the purpose of these awards. For example, it is not uncommonly proposed that a graduate in organic chemistry should use his award to take a course in biochemistry and, at the same time, embark on some biochemical research. This would fall far short of the purpose of these awards. Recipients of awards have made their subsequent careers in teaching and in research in biological and medical departments of universities and in research institutes for biological subjects; two recipients found their way back into physical subjects. Subjects of recipients' first degree (total for scholars, first figure; for bursars, second figure) were: physics (5, 6); chemistry (4, 4); mathematics (2, 2); general sciences (1, -). Subjects studied under award were: physiology (7, 7); zoology (4, 2); botany and zoology, (2, 2); biophysics (-, 1). It is noteworthy that only once since 1952 was botany chosen for postgraduate study. Further information and application forms can be obtained from the Director, the Nuffield Foundation, Nuffield Lodge, Regent's Park, London, N.W.1.

#### Training Course in Taxidermy

THE Museums Association, through the generosity of the Carnegie United Kingdom Trust and in association with several of the major museums, is offering opportunities for, and financial assistance in, training in taxidermy to a limited number of individuals who intend to follow a career in the museum field. The training course will cover a period of three years and candidates should be between the ages of 18 and 25 years and have a sound general education. Forms of application and further information can be obtained from the Secretary, the Museums Association, 87 Charlotte Street, London, W.1. Completed applications should be submitted not later than February 15.

#### University News:

Hull

PROF. R. H. BARBACK has been appointed to the newly established second chair of economics in the Department of Economics and Commerce. The following appointments have also been announced: *Senior Lectureships*, Dr. J. Annett (psychology); G. Richardson (education); *Research Fellowship*, Dr. D. D. Singh (chemistry).

London

THE following titles have been conferred: professor of botany on Dr. Maud B. E. Godward, in respect of her post at Queen Mary College; professor of zoology on Mr. H. R. Hower, in respect of his post at the Imperial College of Science and Technology; professor of oral anatomy on Dr. H. J. J. Blackwood, in respect of his post at the Royal Dental Hospital. Dr. D. A. Mitchison has been appointed reader in bacteriology at the Postgraduate Medical School and Dr. D. A. Walker has been appointed reader in enzymology at the Imperial College of Science and Technology.

Manchester

THE following appointments have been made: *Reader-ships*, Dr. G. Allen (chemistry); Dr. C. N. W. Litting and Dr. G. R. Hoffmann (electrical engineering); D. R. Bland and Dr. S. Levine (mathematics); Dr. S. D. Silvey (statistics in the Department of Mathematics); Dr. G. M. Leak (metallurgy); Dr. A. Herzenberg (theoretical physics); Dr. E. L. Patterson (anatomy); Dr. A. H. Gowenlock (chemical pathology). *Senior Lectureships*, Dr. H. O. Pritchard (chemistry); Dr. F. H. Sumner (computer science); Dr. E. R. Bryan and F. Cheers (engineering); Dr. J. H. Gerrard (mechanics of fluids); Dr. D. St. P. Bunbury (physics); Dr. K. G. Cowling

(agricultural economics); Dr. D. Bulmer (anatomy); Dr. F. B. Beswick (experimental physiology); Dr. S. Thomas (physiology). *Lectureships*, Dr. C. A. Stace (botany); Dr. R. Bryant (chemistry); C. T. Elliott and J. M. Townsend (electrical engineering); P. J. Vermeulen, J. M. Davies, R. C. F. Dye, P. Mason, T. A. Henry, R. J. Aird and W. B. Wilkinson (engineering); Dr. J. E. Pollard (geology); G. Walker, Dr. W. A. Sutherland and Dr. C. E. M. Yates (mathematics); Dr. S. Blairs (metallurgy); G. G. Benson and N. A. Dickinson (pharmacy); Dr. J. W. Murphy and Dr. J. S. Dowker (theoretical physics); E. J. Daintree and Dr. R. J. Long (radio-astronomy); Dr. M. P. Hatton (chemical bacteriology).

#### Newcastle upon Tyne

DR. J. H. D. PRESCOTT has been appointed lecturer in animal production in the School of Agriculture as from December 1, 1964.

#### Reading

THE title of research professor has been conferred on Dr. S. K. Kon, deputy director of the National Institute for Research in Dairying and head of its Department of Nutrition, and on Dr. S. J. Folley, head of the Department of Physiology in the Institute.

#### Announcements

PROF. A. HOLMES has been awarded the Makdougall-Brisbane Prize for the period 1962-64, by the Council of the Royal Society of Edinburgh, in recognition of his contributions to the fundamental philosophy of the Earth sciences.

BRIGADIER R. C. A. EDGE has been appointed director-general of the Ordnance Survey, with the rank of major-general. Brigadier Edge will succeed Major-General A. H. Dowson, who is retiring in September.

DR. H. R. V. ARNSTEIN has been appointed committee secretary, and Prof. K. S. Dodgson meetings secretary, of the Biochemical Society, following the recent retirement of Dr. P. N. Campbell.

ON February 1, the Manchester Office of the Cement and Concrete Association moved into new premises at the following address: Cement and Concrete Association, Television House, 10 Mount Street, Manchester, 2.

VARIAN ASSOCIATES, LTD., have moved to a new address at Russell House, Molesey Road, Walton-on-Thames, Surrey.

AN ordinary meeting of the Scottish Section of the Society for Analytical Chemistry will be held in the University of Strathclyde on February 26. Dr. D. T. Lewis will present a paper entitled "Research Work at the Government Laboratory". Further information can be obtained from the Society for Analytical Chemistry, 14 Belgrave Square, London, S.W.1.

AN exhibition of the Dead Sea Scrolls, arranged by the Smithsonian Institution and sponsored by the Government of Jordan, will be held in the Institution during February 28-March 21. The exhibition will also visit Philadelphia (April 3-25), Berkeley (May 8-30), Los Angeles (June 12-July 5), Omaha (July 17-August 8), and Baltimore (August 21-September 19).

A JOINT meeting of the North of England Section of the Society for Analytical Chemistry and the Newcastle upon Tyne and North East Coast Section of the Royal Institute of Chemistry will be held in Newcastle upon Tyne on February 16. Mr. G. B. Crump will present a paper entitled "Thin-layer Chromatography". Further information can be obtained from the Society for Analytical Chemistry, 14 Belgrave Square, London, S.W.1.

## U.S. NATIONAL SCIENCE FOUNDATION SUPPORT FOR THE DISSEMINATION OF SCIENTIFIC INFORMATION

A PAMPHLET on the dissemination of scientific information, issued by the National Science Foundation\*, outlines the Foundation's programmes to discharge the responsibilities for interchange of scientific information and support of the dissemination of such knowledge placed on it by the Congress Act of 1950, and extended in 1958 by directives from the Congress and from the President. An Act of 1958 also established a Science Information Council to be an advisory group to the Foundation's Office of Science Information Service. The Foundation's programmes have two fundamental objectives: promotion of newer and better techniques for handling and disseminating scientific information, and making existing systems more effective. Its scientific information activities are carried out under five programmes organized in two Sections: the Studies and Support Section, which includes programmes of basic studies, improved processes and systems and support of communication; and the Science Information Co-ordination Section, which includes programmes of Federal science information and of the domestic and foreign science information.

Under the first section, support is provided for research development, experimental application and evaluation of systems of information retrieval, mechanical translations, libraries and publications, with the principal emphasis on improving basic understanding of general problems rather than on establishing particular systems. The Foundation continues to support long-range research on systems for the automatic processing of natural language text with the

eventual aim of mechanizing procedures for indexing, abstracting, organizing and storing information. Research in mechanical translation is a part of this broader field, while, in the work on publication systems, projects have been undertaken to analyse the part played by computers in scientific publication and to investigate machine recording of textual information during the publication of scientific periodicals.

As part of the Foundation's general programme for strengthening the science library network of the country, the information systems programme is seeking ways to improve the effectiveness of those libraries which provide substantial science information services. The publication support programme provides support for journals publishing results of original research, as well as temporary financial assistance for the cover-to-cover and selective translation of research published in Russian, Japanese and Chinese. Any publication considered favourably for support must be making, or showing good promise of making, a significant contribution to the scientific research literature; moreover, its proposed mechanics of publication must be efficient and economically sound.

The principal interests of the programmes for science information co-ordination are to promote non-Federal science information activities in the United States and to co-ordinate these with developments in foreign countries. Two major federal information centres are supported and administered. The first is the Science Information Exchange, which acts as a clearing house for information on current research, while the second is the National Referral Center for Science and Technology, located at the Library of Congress.

## RESEARCH ON SHELTER IN AGRICULTURE AND HORTICULTURE

THE effects of exposure to wind are of direct concern to agriculture, horticulture and forestry, and the practice of using shelterbelts and non-living windbreaks to reduce local levels of wind is of long standing. The broad picture of reduced windiness, altered microclimatic conditions and improved production of crops in the vicinity of windbreaks is generally established; the detailed analysis of these influences is, however, still incomplete. Research into the effects of shelter on microclimate and crop yields began in the early years of this century in a few countries, gained momentum in the United States and U.S.S.R. during the 1930's and, after 1945, attracted much wider interest and support. Early research was concentrated on determining the most suitable type of windbreak for a particular situation and providing a local measure of the benefit likely to be derived from shelter. More recently, it has become necessary for a more fundamental approach to the understanding of the nature and value of shelter: better definition of the physical environment near the ground arising as a result of shelter, and of the relationships between environment and biological processes in both crops and animals. Consequently, it is appreciated that further developments in the field of shelter research must be reviewed periodically in the light of developments in other environmental studies such as agronomy, ecology, micro-meteorology, plant and animal physiology and nutrition.

In order to provide for closer communication between research workers in the various fields relevant to the ques-

tion of shelter, the Ministry of Agriculture, Fisheries and Food, through its Shelter Research Planning Group (now Shelter Research Committee), arranged a first symposium on shelter research at Aberystwyth in 1962 (*Nature*, 194, 1130; 1962). The success of this venture led to a second symposium arranged in co-operation with the Department of Agriculture and Fisheries for Scotland and held at Edinburgh on September 15-16, 1964.

In the second symposium, sessions were again divided between horticultural and field crop aspects of shelter, meteorological developments associated with shelter, and shelter in relation to livestock. In a paper on wind speed and plant growth, Dr. R. M. Wadsworth (University of Reading) dealt with the effect of wind on plant environment and on plant growth as measured by such parameters as relative growth rate, net assimilation rate and leaf-area ratio. Laboratory experiments under controlled wind conditions have suggested that the optimum wind speed for plant growth varies according to other environmental conditions, being between 0.5 and 3 m/sec for very favourable conditions and lower for less favourable conditions. Since wind affects growth to a greater extent when plants are isolated, windbreaks may be more essential in the early life of a crop than later. Low light intensities may also suggest a greater need for wind reduction, whereas light winds are likely to prove increasingly beneficial as light intensity increases in order to prevent reduction in CO<sub>2</sub> availability.

Mr. W. H. Hogg (Meteorological Office, Bristol) reviewed recent horticultural investigations at Rosewarne and Stockbridge House Experimental Horticultural Stations. At Rosewarne, variations in the local climate between shelter hedges have been observed over a 3-year period. Although higher rates of wind speed and evaporation than at the control station were found with certain wind directions, air temperatures and soil temperatures at 2-, 4- and 8-in. depths were consistently higher than in the controls. At Stockbridge House changes in the degree of shelter in relation to the height growth of a young shelterbelt are being examined.

On the subject of shelter effect on crops, Prof. J. N. Black (Department of Forestry and Natural Resources, University of Edinburgh) pointed out that the Agricultural Research Council was financing a new research programme at Edinburgh, which it was hoped would reveal the role of wind in limiting crop production in the exposed arable and pastoral areas. Reviewing previous work in this field from the point of view of future investigations on crop aspects, Dr. J. M. Caborn (University of Edinburgh) suggested that it was necessary to explore the manner in which environmental changes near windbreaks are translated into crop growth and development. A suitable approach might be a detailed study of the heat and water balance of a sheltered area in conjunction with growth analysis of the protected crop.

In the livestock shelter session, papers were presented on present research projects at the Hannah Dairy Research Institute, the Hill Farming Research Organization and the Rowett Research Institute. Drs. K. L. Blaxter, J. P. Joyce and A. J. F. Webster (Hannah) discussed four aspects of their investigations of environmental stress in sheep and cattle: the effect of wind and rain on metabolism; radiation heat loads on sheep as related to incident radiation on a horizontal surface; the time taken by sheep to attain metabolic equilibrium on exposure to cold; and the derivation of a general equation for estimating the thermal demand of an environment. The effects of heavy rain and of wind are approximately similar so far as heat losses are concerned, and the immediate effect of heavy rain has been found to increase heat production by about 30 per cent, provided the ambient temperature is below the animal's critical temperature. The heat derived from total solar radiation at 55° North under clear

skies in mid-winter appears to be about a quarter of that produced by metabolism, whereas in mid-summer it is 10 times as great. Part of the cold stress in Scotland may stem from overcast conditions and consequent diminution of the heating effect of solar radiation. Heavily fleeced sheep also take a longer time than shorn animals to adjust to cold. It is encouraging to note that a rational formula has now been derived which enables heat losses of sheep to be predicted from fleece length, solar radiation, air temperature and wind velocity.

Turning to management aspects, Dr. J. M. Doney (Hill Farming Research Organization) felt that the response to climatic exposure, both physiological and in terms of economic production, was complicated by the nature of the annual cycle of nutrient intake and by the animal genotype involved. At levels of production provided by prevailing hill farm management systems, centred around the present well-adapted hill breeds, the provision of shelter could be quite uneconomic in terms of production increase; on the other hand, changes in management affecting the annual nutrient cycle might demand a change of breed structure and, hence, of the need for shelter. Dr. E. Cresswell (Rowett) reported that energy conservation, in the form of better gains and/or less food consumption, in fattening sheep provided with shelter had not been found so far in their studies. In the discussion which followed it was suggested that, although much of the research in this field so far has concentrated on shelter for the animal, more attention might be given to improving the herbage on hill land, and in this context shelter might be important.

Dr. R. W. Gloyne (Meteorological Office, Edinburgh) surveyed recent developments in instrumentation available for field experiments on shelter and the problems of analysis of data from long-term investigations of the influence of a series of shelterbelts on the climate of a previously exposed hill in North Wales.

In a closing address, the chairman of the Shelter Research Committee, Mr. R. G. A. Lofthouse, referred to the value of these meetings in co-ordinating research related directly or indirectly to shelter, in exchanging information and ideas and, particularly, in reviewing from time to time the present state of research and future needs.

J. M. CABORN

## WEIGHTS AND MEASURES TWELFTH GENERAL CONFERENCE

THE twelfth General Conference of Weights and Measures was held at the Centre International des Conférences in Paris during October 6-13, 1964, under the chairmanship of M. Poivilliers, President of the Paris Academy of Sciences, and was opened by M. Louis Joxe, Minister of State, deputizing for the Minister of Foreign Affairs of the French Republic. Delegations from 37 of the 40 States signatory to the Metric Convention took part in the conference, the United Kingdom being represented by the Director of the National Physical Laboratory and the Superintendent of the Standards Division, National Physical Laboratory. The business of the conference is best summarized by reference to the ten resolutions which were adopted; six were concerned with units and standards of measurement and the remainder with administrative and financial matters.

In the first category the most important was resolution 5 (standard of time-interval) which expressed the need to adopt an atomic or molecular frequency standard for accurate measurements of time-interval but stated that, despite the advances made with the caesium frequency standard, the moment had not yet come to discard the astronomical definition of the second\*. This was because

the hydrogen atom (and possibly the thallium atom) might furnish a standard more precise even than the caesium atom, which already provides a frequency standard reproducible in different laboratories to the order of 1 part in  $10^{11}$  (equivalent to 1 sec in 3,000 years). Nevertheless, as recognition of the use of atomic and molecular frequency standards in physical measurements of time could not be further delayed, the resolution authorized the International Committee of Weights and Measures to designate atomic or molecular standards for temporary usage for this purpose; it also invited those organizations and laboratories which are expert in this field to continue their investigations so that a final recommendation for an atomic or molecular definition of the second may be prepared in due course.

In the declaration made later by the International Committee the first standard to be so designated is the transition between the hyperfine energy levels  $F =$

\* The second, adopted by the International Committee of Weights and Measures in 1956 and ratified by the Eleventh General Conference in 1960, is equal to the fraction  $1/81\,558\,925\,974\,7$  of the tropical year for 1900, January 0 at 12 h ephemeris time. This ephemeris second is made available in practice with the aid of atomic clocks, but only retrospectively as an average value over several years, by means of observations of lunar position; it is reproducible at present to the order of 2 parts in  $10^9$ .

4,  $M = 0$  and  $F = 3$ ,  $M = 0$  of the fundamental state  $^2S_{1/2}$  of the atom of caesium-133 unperturbed by external fields; the value assigned to the frequency of this transition is 9 192 631 770 hertz (c/s) (ref. 1). The resolution represents a major step towards the adoption of an atomic constant as the universal basis of time measurement. Effectively it means that for all purposes in physics, and some in astronomy, the caesium transition is recognized as the present basic standard, but the resolution is so drafted that it will be easy to change from the caesium transition to the hydrogen transition if, for instance, the latter should prove in due course to be superior.

Resolution 6 (the litre) abolished the definition of the litre established in 1901 by the third General Conference, declared that the word 'litre' can be used as a special name given to the cubic decimetre and recommended that the name 'litre' shall not be used to express the results of volume measurements of high precision.

The litre was the name given to the cubic decimetre when the metric system was established during the last decade of the eighteenth century and it now reverts to its original meaning. The intention is that this litre shall only be used for ordinary transactions in trade and not for scientific purposes. The experimental evidence is that the litre, re-defined in 1901 as the volume occupied by 1-kg mass of water at its maximum density, is 28 parts in a million larger than the cubic decimetre (1 litre = 1.000 028 dm<sup>3</sup>). The litre of 1901 is, moreover, a unit which is non-coherent with the International System (SI) of Units (see British Standard 3763: 1964), in which the cubic metre, its multiples and sub-multiples, constitute the reference for volume measurements.

Resolution 7 defined the curie (symbol Ci) as having the value  $3.7 \times 10^{10}$  s<sup>-1</sup>. The curie, although non-coherent with SI units—the SI unit of activity is the reciprocal second (s<sup>-1</sup>)—has been recognized because of its universal use for practical measurements of the activity of radionuclides.

Resolution 8 (unit prefixes) added 'femto' and 'atto' to the list of recognized prefixes forming submultiples of the SI units. Both words are of Danish origin; femto represents the factor  $10^{-15}$ , symbol *f*, and atto the factor  $10^{-18}$ , symbol *a*.

Resolution 9 (gyromagnetic ratio of the proton) invited the national laboratories and international specialists in the determination of atomic constants to continue studies of the gyromagnetic ratio of the proton with the object of establishing the precise value of this constant for application to improving the reproducibility of the ampere, a basic SI unit.

One method of measuring the proton gyromagnetic ratio is to observe the frequency of free precession of protons (in water) in the calculable magnetic field of a coil carrying a known current. The interest thus lies in improving the method, establishing the value of the constant accurate to 1 part in a million or better, and then using the method to maintain the ampere. The ampere is realized absolutely in terms of the metre, the kilogramme and the second by weighing the forces exerted between current-carrying coils of measured dimensions and disposition; maintenance by this method is laborious and inconvenient, and in the best circumstances the reproducibility obtained in different laboratories is not better than a few parts in a million.

Resolution 10 (International Practical Scale of Temperature, IPST) directed attention to the pressing need to revise the IPST of 1948 (as amended in 1960) and to extend the scale below the present limit at the boiling-point of oxygen ( $-182.97^\circ$  C) down to the boiling-points of hydrogen and helium. It recognized that much work has yet to be done in order that the International Committee may recommend the adoption of a new definition of the scale at the next ordinary General Conference, expected to be convened in 1968. The resolution invited the national

laboratories and international specialists in this field to concentrate especially on the following projects: (1) gas thermometry throughout the whole range applicable to the method, including studies of the expansion coefficient of bulb materials especially at high temperatures; (2) measurements of black-body radiation between  $630^\circ$  C and  $1,063^\circ$  C; (3) formulation of a platinum resistance thermometer scale between  $630^\circ$  C and  $1,063^\circ$  C to replace the thermocouple scale specified in the existing scale; (4) verification of the table of values of 'reduced' resistance of platinum below  $0^\circ$  C, including a study of the calibration procedure for platinum resistance thermometers; and (5) new determinations of the boiling-point of oxygen.

Turning now to the administrative and financial resolutions, the first approved the actions taken by the International Committee to establish laboratories and a section at the Bureau International des Poids et Mesures (BIPM) for work on the basic metrology of the ionizing radiations<sup>a</sup>, and invited the committee to continue the work at the BIPM. Resolution 2 recognized the need to complete the constructional work on the new laboratories and to purchase the basic equipment still required for the scientific programme of the section. Provision was made to meet this need by granting a third special contribution of 850,000 gold francs (£100,000) to be paid to the BIPM by Governments in accordance with the same rules as apply to the repatriation of the annual subvention for maintenance of the BIPM.

Resolutions 3 and 4 (annual subvention to the BIPM) referred to the conference convocation document, issued to Governments by the International Committee in December 1963, which described the modern functions of the BIPM and gave an assessment of the basic monetary requirements for proper maintenance and development of its scientific activities. This document also announced that a proposal would be submitted by the International Committee to the General Conference for an increase of the total annual subvention from the present 900,000 gold francs to 1,750,000 gold francs (£204,000) for the 4-year period 1965–68. When the resolution containing this proposal was submitted for discussion at the conference, two delegations announced that their Governments could not agree to such an increase in the annual subvention on the case put forward by the International Committee. Eventually a compromise resolution (No. 4), proposing a graded increase in the annual subvention rising to 1,750,000 gold francs during 1967 and 1968, received qualified approval (16 votes in favour, 20 abstentions and no contrary vote). The Governments whose delegations abstained from voting were committed to deciding one way or the other by December 31, 1964. If only a single contrary vote is received, the resolution becomes void and an extraordinary General Conference must be convened as soon as possible to consider the finances of the BIPM, which temporarily finds itself in a most unsatisfactory and uncertain position for planning its future programme.

The International Committee, which is responsible for management of the BIPM and for the organization of the General Conference, held meetings during October 1–13. The Committee decided to establish a new advisory committee (comité consultatif) to deal with units of measurement. This step has become essential to ensure that the best advice is received on all questions relating to units of measurement from other specially interested organizations, which will be invited to appoint representatives on the committee. The main task is to consider the improvement and development of the SI units and to make recommendations for their extension to cover all fields of measurement of physical quantities. There are six other advisory committees dealing respectively with length (definition of the metre), time (definition of the second), electricity, temperature, photometry and standards of measurement for the ionizing radiations.

Under the auspices of the International Committee international journal of metrology, *Metrologia*, commenced quarterly publication by Springer in January 1965. The general editor is Dr. L. E. Howlett (National Research Council, Ottawa), chairman of the International

Committee, who is assisted by an international editorial board.

## NON-CUTTING USES OF INDUSTRIAL DIAMONDS

**M**OST industrial diamonds are used for cutting purposes where the objective is removal or displacement of relatively hard materials such as metal or rock. There are, however, other important applications of these diamonds which are not so well known, in particular 'non-cutting' uses. In this category are recognized mechanical and non-mechanical applications; the former include processes where the diamond is employed as an integral working part of a machine; the latter implies those instances where it is performing other independent functions. A recently issued publication entitled *Non-Cutting Uses of Industrial Diamonds*\* briefly describes and illustrates some of the more important non-cutting applications of these diamonds.

In the category of mechanical uses are styli, what are known as 'feeler' styli, diamond distance stops, gramophone styli and bearings. All these uses depend on the factor of extreme hardness of diamond and the facility with which it can be shaped and polished to a very high degree of accuracy and tolerance for the particular purpose in view, with the assurance of retention of shape and high surface finish for a far longer time than any other material. Feeler styli are employed as sensitive feelers in a wide variety of surface measuring instruments; they are ground

into cone shape and have an accurate radius polished on the tip; for example, high-resolution types of feeler styli have a tip radius of 0.00005 in. Diamond distance stops are used in distance pieces to ensure accuracy in lapping and honing operations in cases where the finished work-piece is to be of pre-determined thickness. With gramophone styli the diamonds are ground to cone shape and the tip polished to a radius varying according to the type of record to be produced or played; styli for microgroove- and stereo-records require far finer tips than those used to play the old standard 78-r.p.m. records.

As an example of their use as bearings, precision watch-making may be cited, where in such fine mechanisms diamonds replace natural or synthetic ruby, especially in cases demanding accuracy, long life and frictionless bearings. In the category of non-mechanical applications there are optical uses, electronic functions, and diamond-tipped indenters, such as are used on some hardness testing machines. In the optical field, the diamonds must be of gem quality, clear as optical glass. Electronic applications chiefly concern the use of semiconducting diamonds which have proved extremely efficient as sensitive detector heads in thermistor equipment; they can also be used as radiation counters; for this purpose only very small diamonds are used, and since they are chemically inert they make eminently suitable implant detectors in the living body, apparently without any harmful effects.

## ANGULAR SIZES OF THE X-RAY SOURCES IN SCORPIO AND SAGITTARIUS

By M. ODA\*, G. CLARK, G. GARMIRE and M. WADA†

Laboratory for Nuclear Science, Massachusetts Institute of Technology, Cambridge, Massachusetts

AND

PROF. R. GIACCONI, DR. H. GURSKY and J. WATERS

American Science and Engineering Inc., Cambridge, Massachusetts

**T**HE angular diameters of the X-ray source regions in the constellations Scorpio and Sagittarius respectively have been investigated in two rocket experiments conducted on August 28, 1964 (flight I), and October 24, 1964 (flight II), at the White Sands Missile Range. These sources were first observed by Giacconi *et al.*<sup>1</sup> as a single unresolved source of cosmic X-rays with wave-lengths around 3 Å and located near the galactic centre. Subsequent observations by Friedman *et al.*<sup>2</sup> and by Giacconi *et al.*<sup>3</sup> established the existence of two separate sources, in this part of the sky, one located near right ascension 16<sup>h</sup> 15<sup>m</sup>, declination - 15°, and the other near or coincident with the radio centre of the galaxy. In the present experiments we observed these two sources with a detector using a special collimator which has a high angular resolving power and at the same time a large field of view.

Flight I was launched at a sidereal time of 20 h 56 min, and flight II at a sidereal time of 20 h 20 min. In both flights, the rocket motion consisted of a rapid spin about

its long axis and a slow precession of the long axis around a yaw cone of small opening angle. The detectors themselves were banks of Geiger-Müller tubes with beryllium windows 0.002 in. thick. Each bank had a sensitive area of approximately 100 cm<sup>2</sup>. The collimators, which have been described elsewhere<sup>4</sup>, consist of two grids of parallel wires. Each wire is separated from the adjacent wires by slightly less than one wire diameter, and the two grids are mounted one in the back of the other and separated by a distance of 1.5 in. (as dictated by the available space in the instrument section of the rocket). Parallel radiation falling on the collimator casts a shadow of the wires forming the front grid on to the back grid. The transmission of the incident radiation passing through the back grid and into the detectors is determined by whether the shadow coincides with the back wires or with the openings between. As the apparatus is rotated around an axis parallel to the wires, the intensity transmitted by the collimator is modulated in a way that is determined by the dimensions of the wire grids and the rate of rotation. On the other

\* On leave from the Institute for Nuclear Study, University of Tokyo.

† On leave from the Institute of Physical and Chemical Research, Tokyo.

Fig. 1. Modulation of X-ray flux from the Scorpio source

hand, if the incident radiation is not parallel, as in the case of radiation from an extended source, then the shadow is diffuse, and the degree of modulation observed as the collimator is rotated is correspondingly reduced. It is apparent that the modulation is large or small depending on whether the angular size of the source is large or small compared with the effective angular resolution which is the angle subtended by a wire diameter at the distance of separation between the two grids in the collimator. In this experiment the rotation of the collimator was provided by the motion of the rocket and the angular resolutions of the two collimators were  $1/2^\circ$  and  $1/8^\circ$ , respectively, for flight I, and  $1/2^\circ$  for flight II.

The collimators for flight I were provided with baffles parallel to the spin axis of the rocket defining a field of view with a  $30^\circ$  full width and a triangular response. The wires of the collimator were tilted at an angle to the spin axis in such a way as to produce three modulation cycles as a source crossed the  $30^\circ$  field of view of the baffles. The orientation of the collimator was such that it measured the size of a source in the direction parallel to the spin axis of the rocket.

Because the Scorpio source provided only about five counts per spin and the rocket's motion was complicated by the precession of the spin axis, it was necessary to analyse the aspect of the rocket in detail before it was possible to combine data from each spin. Fig. 1 shows the superposition of about 200 sec of flight after corrections have been made for the shift in phase of the modulation pattern caused by the precession of the spin axis. It is clear that there is a modulation of the X-ray flux due to the

change of relative elevation of the Scorpio source with respect to the detector. The arrows indicate the expected positions of the minima in the modulation pattern as determined from the design parameters of the collimator. The dashed lines represent the expected modulation for a source of less than  $1/2^\circ$  and  $1/8^\circ$  angular diameter respectively, including the smearing effect of the background radiation and the partial transmission of the  $1/8^\circ$  collimator for a point source.

In flight II the collimator had an angular resolution of  $1/2^\circ$  and was provided with a narrower field of view with a  $15^\circ$  full width in order that the two source regions would be well separated. The wires this time were made perpendicular to the direction of the spin axis of the rocket. The modulation was thus expected to occur not as the result of the rotation of the rocket, but rather as the result of the variation in the elevation of the source with respect to the collimator axis caused by the precession of the rocket's spin axis. The source was seen 5 times during one yaw cycle. It is estimated that at least 90 per cent of the flux at the maximum is obscured at the minimum.

Similar analyses were made for the Sagittarius source region. The modulation is not so clear as in the case of the Scorpio source. A test analysis of artificial data generated by Monte Carlo simulation, with the isotropic background taken into consideration, showed that, in spite of the smearing effect of the background, a true modulation should have been clearly seen. The failure to observe a clear modulation, therefore, leads to the conclusion that the Sagittarius source is an extended source, or several sources distributed within a region of angular diameter larger than the resolution of the collimator.

We conclude from the foregoing analysis that the extension of the Scorpio source along the direction approximately parallel with the galactic plane is definitely less than  $1/2^\circ$  and probably smaller than  $1/8^\circ$ . Although we cannot rule out the possibility that the source extends in the direction perpendicular to the galactic plane, the fact that the modulation was seen throughout all phases of the yaw cycle while the axis of the rocket varied by  $25^\circ$  sets an upper limit of about  $1^\circ$  along the perpendicular direction to the galactic plane. We also conclude that the flux from Sagittarius does not all come from a single point source. Rather, it is spread over a region more than  $30$  min of arc in diameter and is either an extended source or is composed of more than a single source.

We are grateful to Prof. Bruno Rossi for many helpful discussions in connexion with this experiment.

## GEOCHEMICAL CONSTANTS FOR RUBIDIUM AND STRONTIUM IN BASIC ROCKS

By DR. AKIMASA MASUDA

University of Tokyo, Tanashi P.O., Tokyo

WE have developed a new approach<sup>1-3</sup> for deriving some geochemical constants from variation of abundance of elements in silicate material. Factors essential to this theoretical treatment are initial concentration, partition coefficient, and liquid fraction value. For two or three

elements, if data are available on their abundances it is sometimes possible to deduce their initial abundances and their partition coefficients. Actually, this line of investigation led us to some success in a theoretical consideration<sup>2-4</sup> of the distribution of thorium, uranium, and lead within

the Earth. The present attempt is aimed at applying the same logic to the problem of abundance of rubidium and strontium in the Earth.

As shown elsewhere<sup>1-5</sup> there are two conjugate types of silicate materials within the Earth, namely, liquid and solid. (The genesis of the Earth's mantle is assumed to have proceeded in such a way that the concentration ratio of any minor element between solid and liquid phases in equilibrium was constant.) The following general formulae hold for primary liquid and solid types, respectively:

$$\log C = \log C^0 - (1 - k) \log f_w \quad (1)$$

$$\log C' = \log C^0 + \log k - (1 - k) \log f_w \quad (2)$$

where  $C^0$  is the initial concentration,  $C$  the concentration in liquid-type material with liquid fraction value of  $f_w$ ,  $C'$  the concentration in the corresponding solid-type material, and  $k$  the partition coefficient (which is equal to  $C'/C$  in the equilibrium system). Application of these general formulae to a combination of rubidium and strontium yields:

$$\log C_{Sr} = b \log C_{Rb} + \log C^0_{Sr} - b \log C^0_{Rb} \quad (3)$$

$$\log C'_{Sr} = b \log C'_{Rb} + \log (k_{Sr} C^0_{Sr}) - b \log (k_{Rb} C^0_{Rb}) \quad (4)$$

where:

$$b = (1 - k_{Sr}) / (1 - k_{Rb}) \quad (5)$$

Therefore, when we deal with the materials which separate perfectly into liquid and solid phases and when abundances of two elements, for example, rubidium and strontium, in such materials are plotted on a diagram of logarithmic scales, we gain two straight lines, 'liquid' and 'solid', running parallel to each other. If the separation of the phases is imperfect, some points may be found in the zone between these two lines. In addition, secondary partial melting or repetition of melting and crystallization may complicate or obscure the simple features which should otherwise be found in such a diagram.

With these in mind, let us direct our attention to a relation (see Fig. 1) of the abundances of rubidium and strontium as determined by Faure and Hurley<sup>6</sup> for basic rocks by the method of isotope dilution. Here we shall assume as a working hypothesis that Nos. 1, 2, 3 and 4 belong to a typical solid type, while the specimens such as Nos. 5, 13, 10, etc., are of a typical liquid type. (As to such deviations as seen for Nos. 11 and 12, an interpretation will be given later on.) To make the calculation easy, it is assumed that the solid-type line passes through No. 1, while the liquid-type line passes through No. 5. The value of the slope of such a correlating line is of fundamental significance to any estimate of basic constants, because the value of the slope corresponds to  $b$  as defined in equation (5). In Fig. 1 it appears that two slopes are possible; the slope of the line joining No. 1 and No. 3 is 0.735 and that of the line joining No. 5 and No. 7 is 0.865. Since it is believed that the true value of  $b$  is related to the range of these values of slope, or very closely associated with it, two series of theoretical calculation will be undertaken based on these two values. If  $b$  is taken to be 0.735 (Series I), the solid line passing through No. 1 can be expressed as:

$$\log C'_{Sr} = 0.735 \log C'_{Rb} + 1.871 \quad (6)$$

and the corresponding liquid line which passes No. 5 becomes:

$$\log C_{Sr} = 0.735 \log C_{Rb} + 1.564 \quad (7)$$

As evidenced by equations (3) and (4) and from equations (6) and (7):

$$1.871 - 1.564 = 0.307 = \log k_{Sr} - 0.735 \log k_{Rb} \quad (8)$$

$$b = 0.735 = (1 - k_{Sr}) / (1 - k_{Rb}) \quad (9)$$

Solving equations (8) and (9) diagrammatically gives values for  $k_{Rb}$  of 0.084 and  $k_{Sr}$  of 0.33. If a similar calculation is made using a value of 0.865 for  $b$  (Series II), we obtain values for  $k_{Rb}$  of 0.066 and  $k_{Sr}$  of 0.19.

Fig. 1. The abundance relationship between strontium and rubidium in basic rocks. Nos. 1-4 are from Hawaiian Islands and Nos. 5-7 from Samoan Islands<sup>6</sup>. The slope drawn in this diagram is 0.735, that is, Series I.

Now let us estimate the initial abundances of rubidium and strontium. For this purpose, it is convenient to deal with the average abundances in basic rocks, because the liquid fraction value for the average basic rock has been estimated to be about 1/80 (ref. 2). As seen in Fig. 1, the point representing the abundances (rubidium 30 p.p.m., and strontium 465 p.p.m.) given by Turekian and Wedepohl<sup>7</sup> for the average basic rock (No. 13) falls almost on the liquid-type line. In this article we shall use abundance values for rubidium of 31 p.p.m. and for strontium of 460 p.p.m. for the average basic rock, for the corresponding point falls just on the liquid line of Series I, even though this modification of abundances has a very slight effect on a result of the calculation. For a set of partition coefficients for  $k_{Rb}$  of 0.084 and  $k_{Sr}$  of 0.33 according to  $b = 0.735$ , we gain the equations (cf. equation (1)):

$$\log 31 = \log C^0_{Rb} - (1 - 0.084) \log (1/80) \quad (10)$$

$$\log 460 = \log C^0_{Sr} - (1 - 0.33) \log (1/80) \quad (11)$$

From these equations, we obtain values for  $C^0_{Rb}$  of 0.56 p.p.m. and  $C^0_{Sr}$  of 24 p.p.m., respectively. For Series II, values for  $C^0_{Rb}$  of 0.51 p.p.m. and  $C^0_{Sr}$  of 13 p.p.m. are obtained. (The corresponding values of  $\bar{R}$  are shown in Table 1, where  $\bar{R}$  refers to the abundance ratio of average basic rock to initial matter.) It is of considerable interest to compare these resulting values with the abundances in chondrites. The chondritic abundance of rubidium is known to be 3 p.p.m. (ref. 8). This suggests that the effective initial concentration of rubidium for the Earth's 'oxide sphere' was much less than for the chondrite. This result is also in good agreement with the conclusion gained from a combined treatment<sup>9</sup> of strontium isotopes and lanthanides. Although Gast<sup>10</sup> did not take into account the partition coefficient and hence his deduction is not quite exact, he first pointed out the possibility of depletion of rubidium relative to strontium in the Earth when making comparisons with chondrites. As to strontium, on the other hand, its initial concentration derived from Series II is almost equal to the chondritic concentration (11 p.p.m.) determined by Pinson *et al.*<sup>11</sup>, while the corresponding value from Series I is almost equal to the concentrations of strontium in meteorites adopted by Goldschmidt<sup>12</sup>, Urey<sup>13</sup>, and Levin *et al.*<sup>14</sup>. These authors

Table 1. PARTITION COEFFICIENT, INITIAL CONCENTRATION, AND THE ENRICHMENT FACTOR FOR AVERAGE BASIC ROCK

	Series I		Series II	
	Rb	Sr	Rb	Sr
$k$	0.084	0.33	0.066	0.19
$C^0$ (p.p.m.)	0.56	24.4	0.51	13.2
$\bar{R}$	55.3	18.8	60.8	34.8

adopted, respectively, 20, 23 and 22 p.p.m. (As the chondrite might contain on an average 16.8 per cent non-oxide components<sup>18</sup>, the effective concentration of oxyphile element in the oxide phase of the chondrite is considered to be 1.20 times the apparent concentration in the whole chondrite.) So far as such a comparison is concerned, it is difficult to decide which value of initial strontium concentration is preferable or which value of  $b$  is appropriate. For reasons which will be mentioned later, however, the value of Series I seems to be advantageous—not decisively but slightly.

It was fortunate that the rocks analysed by Faure and Hurley for rubidium and strontium involved the eclogite (No. 10) from the Robert Victor Mine, South Africa, for the concentrations of lanthanides in this rock were determined by Schmitt *et al.*<sup>18</sup>, and the liquid fraction value for it has been estimated by us from the analysis of the lanthanide pattern. According to our estimation<sup>17</sup>,  $\log f_w$  for this eclogite has a value of  $-1.204$ . (Note that the value of liquid fraction is a value assigned to the rock, and not dependent on the species of chemical elements contained therein.) Since the initial concentration and partition coefficient necessary for equation (1) have already been obtained for each series of calculation, we can evaluate the liquid fraction value for the eclogite in question by introducing the observed abundances (rubidium 6.90 p.p.m., and strontium 149 p.p.m., ref. 6) into equation (1). Table 2 shows the result of the calculation. (Disagreement between the values obtained from rubidium and strontium is due to the fact that the point representing the observed abundances does not fall strictly on the representative liquid-type line passing No. 5.) It is seen in Table 2 that Series I gives the liquid fraction value closer to that obtained from lanthanides than Series II. Hence it is thought that  $b = 0.735$  (Series I) is closer to the true value than  $b = 0.865$  (Series II).

It is of interest to plot the obtained value of  $\bar{R}$  in a diagram<sup>15</sup> where the abundance ratio of average basic rock to average oxide phase of chondrite has been plotted against the reciprocal of the ionic radius (see

Fig. 2. Enrichment factor (ordinate) between average basic rock and average oxide phase of chondrite as a function of reciprocal (abscissa) of ionic radius<sup>15,16</sup>. However, the abundances of lanthanides are for shales analysed by Minami<sup>18</sup>.

Table 2. LOGARITHM OF LIQUID FRACTION VALUE FOR ECOLOGITE, ROBERT VICTOR MINE, SOUTH AFRICA

Series I		Series II	
Rb	Sr	Rb	Sr
-1.180	-1.185	-1.207	-1.314

(The corresponding value from lanthanides is  $-1.204$ )

Fig. 2). (In this diagram the points for  $\bar{R}$  of Series I are shown as open circles.) It can be seen in Fig. 1 that the deviation of an open circle for strontium from the extrapolation of the join calcium-magnesium is small in comparison with the solid circle. This may also suggest that the value for  $C_{Sr}^0$  of 24 p.p.m. (Series I) is preferable to  $C_{Sr}^0$  of 13 p.p.m. (Series II). Meanwhile, it is a remarkable fact that the value of  $\bar{R}$  obtained here for rubidium falls close to the main trend of the polyvalent elements. It is felt that the calculated value of  $\bar{R}$  for rubidium reflects the actual effect, and the alkali metals are thought to be exceptional in that their abundances in chondrites are not necessarily equal to their initial effective concentrations in relation to the process of formation of Earth's mantle, as suggested by Gast<sup>10</sup>.

According to the data presented by Faure and Hurley<sup>6</sup>, the rubidium/strontium ratios calculated from  $^{87}\text{Sr}/^{86}\text{Sr}$  are in accordance with the directly measured rubidium/strontium ratios (see Table 3). However, the discordance is exceptionally large for basic rocks from the Mid-Atlantic Ridge and Columbia River, Oregon. However, this can be explained by assuming that these two basalts were produced by partial melting of primary liquid-type material. It should be noted that, while the rubidium/strontium ratio in the product of partial melting differs from that in the parent material, the  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio reflecting the rubidium/strontium ratio in the parent material is passed on to the product of partial melting. (Actually, a similar case was found with respect to Th/U ratio and to  $^{206}\text{Pb}/^{207}\text{Pb}$  ratio of alkali rock, Japan<sup>19</sup>.) Since the partition coefficients for rubidium and strontium have been evaluated here, we can estimate the rubidium/strontium ratio pertaining to the source material for the product of partial melting. In Fig. 3, a conjugate relation between solid and liquid in equilibrium is shown by the broken line; the slope of a conjugate line must be equal to  $\log k_{Sr}/\log k_{Rb}$ . This line also indicates the contemporaneous or commensal relationship for hybrids of conjugate solid and liquid. (The chain line in Fig. 3 indicates the liquid line relative to the primary liquid-type material.) Thus, the parent material for the basalt boulder from the Mid-Atlantic Ridge (No. 11) is estimated to correspond to  $P$ , while that for the basalt from Columbia River (No. 12) is estimated to be  $Q$ . According to Series I, the rubidium/strontium ratios for  $P$  and  $Q$  are 0.030 and 0.036, respectively. If the same correction is made for a rather small deviation of Deccan Plateau basalt (No. 9), we obtain 0.046 as the theoretically corrected value of rubidium/strontium ratio. Similar estimations can be made for Series II. In Table 4 the estimated ratios for parent materials are listed. It can be seen that the agreement between the isotopically estimated ratio and the theoretically corrected one is good. The agreement is especially

Table 3. COMPARISON OF ISOTOPICALLY CALCULATED Rb/Sr RATIO (A) OF THE SOURCE MATERIAL WITH MEASURED Rb/Sr RATIO (B) OF BASALT

Locality	A	B	A/B
Hawaiian Islands (Nos. 1-4)	0.034	0.0240 ~ 0.0375	0.71 ~ 1.10
Samoa Islands (Nos. 5-7)	0.038	0.0445 ~ 0.0733	1.17 ~ 1.93
Ascension Island (No. 8)	0.035	0.0496	1.42

Deccan, India (No. 9)	0.043	0.0885	1.59
Columbia River, Oregon (No. 12)	0.032	0.176	5.50

After Faure and Hurley<sup>6</sup>.

Table 4. COMPARISON OF ISOTOPICALLY CALCULATED Rb/Sr RATIO (A) WITH THEORETICALLY CORRECTED Rb/Sr RATIO (C)

Specimen*	A	C	C/A	Ser. I	Ser. II
No. 11	0.030	0.0300	1.00	1.59	1.59
No. 12	0.032	0.0360	1.12	1.45	1.45
No. 9	0.043	0.0465	1.08	1.44	1.44

\* Compare with Table 3.

Fig. 3. The strontium versus rubidium abundance relation, with conjugate or commensal relationship pertinent to Series I

good for the result of Series I. Thus, in this respect, Series I based on  $b = 0.735$  also gains a slight advantage over Series II (based on  $b = 0.865$ ).

The small difference between calculated and measured (or corrected) rubidium/strontium ratios may be attributed in part to an uncertainty of the  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio for the stage of rise of heterogeneity in the Earth. The depletion of rubidium might have occurred in the Earth's primitive material prior to its main differentiation. If so, it is likely that the primeval  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio for the Earth was somewhat lower than for chondrites.

According to the foregoing correction, the corrected abundances (Series I) of rubidium and strontium for Deccan Plateau basalt are 7.9 and 170 p.p.m., respectively. A calculation of liquid fraction value for these abundances results in  $\log f_w$  equal to  $-1.256$ . On the other hand, the previous calculation<sup>4</sup> relative to isotopic composition of lead indicated that the logarithm of liquid fraction value for the source material of lead in ores averages  $-1.233$ . The mutual closeness of these values is noteworthy, because the common lead of ores is deduced as having originated from continental basalts and because the Deccan Plateau basalt is a representative continental basalt. Conformity between the results from three independent approaches (rubidium-strontium, lanthanides, and lead-uranium-thorium), though starting from one and the same line of thought, can be regarded as a corroboration of our theory.

I thank Dr. Yoshito Matsui for his advice.

## MEASUREMENTS OF NOISE EMISSION FROM MERCURY BALLS

By GEORGE H. SAUM, jun., and WILLIAM H. FISCHER

National Center for Atmospheric Research, Boulder, Colorado

THIS article describes a procedure and shows the results of radio frequency noise emission measurements from two kinds of mercury balls.

A mercury ball<sup>1</sup> is a device consisting of a glass sphere approximately 3 in. in diameter containing a small amount (about 5 cm<sup>3</sup>) of mercury and a gas under low pressure. Of the two balls described, one contained dry air and the other neon. When the neon ball is shaken in the dark it exhibits the characteristic glow of an ionized neon discharge confined to the vicinity of the mercury globule. Simultaneously there is an emission of radio frequency energy which is measurable up through the tens of megacycles when using sensitive equipment in a radio frequency quiet environment.

It is reported<sup>2</sup> that the mercury ball produces electromagnetic oscillations with remarkable regularity at a frequency of 3.4 kc/s. The emitted work was found by Von Halla and Nowotny to be  $3 \times 10^{-11}$  W when the ball was shaken with a terminal velocity of 50 cm/sec.

Inasmuch as the noise emission from mercury balls is relatively small in amplitude, it is desirable to undertake the measurements in an environment as free from extraneous noise as possible. This environment was provided by a 15 ft  $\times$  30 ft. double-shielded room which has an attenuation to electric fields in excess of 120 dB over the frequency range of interest.

Fig. 1 shows a close-up view of the mercury ball mounting arrangement. The ball is attached to a flexible phenolic strip which is clamped in a vice. The phenolic strip has adjustable-length aluminium stiffeners which limit the amplitude of excursion the ball may attain. Compressed air is supplied through the hose and nozzle-valve to a vibrating flapper which amplitude modulates the air column striking the phenolic strip holding the ball. Once the flapper is set in motion it continues to vibrate at a self-adjusted rate dependent on such parameters as air velocity, flapper mass, its lever arm and stiffness. In this particular arrangement it was possible to obtain approximately 0.5 in peak-to-peak ball excursions at a rate of 5–10 c/s. The entire assembly shown in Fig. 1 was placed on a copper-topped work-bench oriented lengthwise in the shielded room.

Fig. 2 shows the placement of the low-frequency noise meter and antenna. The rod antenna is located 3 ft. directly in front of the mercury ball. The noise meter is a Stoddard NM10A which covers the frequency range 14–250 kc/s. This meter measures peak noise values (time constant of detector approximately 600 msec) and is calibrated in terms of dB above 1  $\mu$ V. Ground bonding is accomplished only at the noise meter to avoid multiple loops. This is visible in Fig. 2 at the left side of the meter.

Fig. 1. Mercury ball mounting

Fig. 2. Low-frequency test apparatus

In Fig. 3 the set-up for higher frequency noise measurements is shown. Here the equipment consists of an Empire Devices *NF105* noise meter and a 41-in. vertical antenna. The range of this instrument with the antenna shown is 150 kc/s–30 mc/s. This meter also measures peak noise values and is calibrated by means of a built-in impulse noise generator to read dB above 1  $\mu$ V per megacycle of receiver band-width. The 41-in. vertical antenna with its matching transformer is mounted on a tripod which is attached with a wide copper strap to the front edge of the test bench. This strap provides the only ground point for the measuring instrument. The antenna-to-ball distance was 36 in. at the lower frequencies and 12 in. at the higher frequencies. During the actual measurements the cart containing the noise meter was located some distance behind the set-up to minimize operator interaction.

The test procedure consisted of scanning the frequency spectrum, beginning at 14 kc/s, and recording the noise intensity at a minimum of three points per octave. A variable time was spent at each frequency to record the maximum pulse, since pulse height was not uniform.

The *NM10A* was placed in the 'Peak' detector function with a short charge-long discharge time constant and the operator used the aural slide-back method of matching the unknown pulse amplitude. With this procedure, the readings are in terms of  $\mu$ V (or dB above 1  $\mu$ V) existing at the antenna terminals. The reading may be expressed in terms of band-width by multiplying by the instrument's 'impulse factor' which accounts for the impulse

band-width of the *NM10A* receiver. Expressing the readings in terms of band-width facilitates instrument comparison and allows the data to be plotted as though only one instrument was used.

The *NF105* was also operated in the 'Peak' detector function and in this case the operator chose the visual substitution method of matching the unknown pulse amplitude. In this method the output from a built-in impulse generator is adjusted to match the unknown pulse. The impulse generator was previously calibrated in terms of dB above 1  $\mu$ V/Mc/s instrument band-width.

Since the impulse noise band-width of the *NF105* is automatically taken into account when the impulse generator is used, the readings are in terms of dB above 1  $\mu$ V/Mc/s at the input terminals of the measuring instrument.

A knowledge of the transfer characteristics of the antennae will allow the input voltage to be specified in terms of field intensity,  $\mu$ V/mc/s. The particular transfer characteristic of interest is known as 'effective height'. The determination of a given antenna's effective height while located inside a shielded enclosure and near large metallic objects is difficult and subject to errors of unknown magnitude. In addition, all the measurements took place while in the 'near' field, which increases the error in specifying the results in terms of 'far' field units. Generally, the procedure consists of producing an electromagnetic field of known intensity which is uniform throughout an area containing the unknown antenna. By measuring the open circuit voltage induced in the unknown antenna, the effective height is found from the relation:

$$h = \frac{V}{E} \quad (1)$$

$E$  = electric field (V/m),  $V$  = induced voltage,  $h$  = effective height (metres).

If one ignores the implications of being in the near field, a satisfactory solution for the determination of effective height can be obtained through the following considerations<sup>3,4</sup>:

$$R_{in} = 2.5 (\beta L)^2 \quad (2)$$

With:

$$\beta = \frac{2\pi}{\lambda} \text{ and } L = 2l$$

where  $R_{in}$  is input resistance of a short vertical antenna in ohms,  $\lambda$  is wave-length in meters,  $l$  is physical length in meters:

$$R_{in} = \frac{40\pi^2 l^2}{\lambda^2} \quad (3)$$

Fig. 3. High-frequency test apparatus

for a short vertical antenna above a perfect ground plane. Further:

$$h = \frac{\lambda \sqrt{R_{in}}}{\pi \sqrt{160}} \quad (4)$$

and, on combining, one finds:

$$h = \frac{l}{2} \quad (5)$$

The antenna used with the NM10A was 2.2 m long, making its effective height equal to unity, for practical purposes. Readings obtained when using this antenna can be expressed directly in  $\mu\text{V/m}$  (ref. 5).

The situation, however, is not as clear-cut in the case of the NF 105. The VA 105 antenna has an effective height of 0.5 meter when used with an adequate ground plane. In addition, the antenna contains a matching network which transforms the antenna impedance to 50 ohms. Thus, assuming the match is perfect, the antenna factor would amount to 27 dB (6 dB for effective height + 6 dB for open circuit voltage conversion + 15 dB for transformation ratio). Therefore, 27 dB has been added to the data in order to convert the readings into field intensity.

Fig. 4. Neon ball test results

Fig. 5. Air ball test results

Fig. 6. Joint data results

The results for the mercury ball containing neon are shown in Fig. 4 and those of the mercury ball containing air are shown in Fig. 5. It can be seen that the noise values are not particularly large and have descended into instrument ambient levels near 25 Mc/s. There was no evidence of noise beyond 30 Mc/s from either ball, even though the neon ball had not quite reached instrument ambient.

In order to facilitate analysis of the results, it was decided to fit a smooth curve to the calibrated data. Least-squares logarithmic fit lines were calculated with a CDC 3600 computer using a programme from the NCAR computer-programme library. Linear, quadratic, and cubic fits were called for. Using the logarithmic residuals as criteria of goodness of fit, it was decided that the quadratic curve was the best fit. The cubic fit was only slightly better than the quadratic. The data and the quadratic curve for the averaged data are shown in Fig. 6.

The data were submitted to a non-parametric approximate correlation test similar to the more common sign test<sup>6</sup>. The data were divided into four sections at the points where changes in measuring equipment were made. The first two sections contained three-quarters of the data points. The point-to-point variations in the neon measurements were compared with those in the air measurements. The third and fourth sections were not tested individually since they contained so few points each. No correlation was found in the first or the second sections, but a correlation was found in the first two sections combined. Of the four possible combinations of three sections taken together, correlations were found in the combinations of the first, second and third sections and of the first, second and fourth sections. The other combinations contained either sections one or two, but not both, and no correlations were found in these combinations. All the measurement variations were found to be correlated.

In addition to any sectional or combinational correlation, there is a downward trend in the data, so that one might expect that, as more sections are brought into analysis, a better correlation would be found. It cannot definitely be concluded from this analysis that the measurements are or are not random ones superimposed on a downward trending noise-strength versus frequency line. The variations may be artefacts introduced by the measuring equipment, or they may be real variations in the nature of emission spectrum lines. The resolution of the experimental equipment did not permit a definite decision on this point. The correlation test, however, would appear to indicate that the measurement variations are random ones scattered about a downward trending line.

The balls do not have identical frequency dependencies. This can be attributed to differences in physical construction such as amount of mercury, gas pressure, etc. The variation of noise amplitude with ball parameters is

not known; it forms the basis of investigations which are being continued.

In general, mercury balls, whether containing neon or air, emit electromagnetic radiation of a broadband nature the intensity of which is an inverse function of frequency.

Much of this work was performed while one of us (G. H. S.) was employed by Colorado Research Division of ITT, Broomfield, Colorado.

## RELATIONSHIP BETWEEN GLUTATHIONE STABILITY AND *IN VIVO* SURVIVAL OF AUTOLOGOUS, DEGLYCEROLIZED, RESUSPENDED RED BLOOD CELLS

By LT.-CDR. C. ROBERT VALERI and LINDA E. McCALLUM

U.S. Naval Hospital, Chelsea, Massachusetts

FELGER<sup>1</sup> has reported that marked increase in spontaneous haemolysis occurred *in vitro* when reduced glutathione was 40 per cent or less of its initial value. Benesch *et al.*<sup>2</sup> have shown a relationship between erythrocyte integrity and sulphhydryl groups, in that haemolysis occurs on incubation of red blood cells with various mercurial compounds. Jacob *et al.*<sup>3,4</sup> have reported that the loss of viability of erythrocytes is related to the inhibition of membrane sulphhydryl groups and is unrelated to intracellular sulphhydryl levels *per se* or the overall rate of cellular glycolysis.

Beutler and co-workers<sup>5,6</sup> have reported that erythrocytes susceptible to drug-induced haemolysis *in vivo* are deficient in reduced glutathione (GSH), and manifest glutathione instability as demonstrated by a marked decrease in content of glutathione after incubation with acetylphenylhydrazine. These abnormalities of glutathione metabolism have been attributed to the reduction of glucose-6-phosphate dehydrogenase activity as demonstrated by Carson *et al.*<sup>7</sup>

This paper reports on the relationship of reduced glutathione level, glutathione stability, glucose-6-phosphate dehydrogenase level, and MCV to 24-h and 7-day chromium survival of autologous deglycerolized resuspended erythrocytes.

Blood (approximately 450 ml.) was collected in plastic bags containing acid citrate dextrose (ACD; NIH A) solution, from 28 white and two negro healthy male donors, ages 18–35. The samples were glycerolized and frozen on the day of collection or after 1–12 days of storage at 4° C. The red blood cell mass and the plasma of each sample were separated and the intracellular preservative, glycerol, was added to the red blood cells by the closed, continuous, sterile centrifugation process using the Cohn fractionator. This process has been reported by Haynes *et al.*<sup>8</sup> The glycerolized red blood cells were frozen slowly to –80° C and stored for 1–2 months. On the day of reconstitution, the preserved red blood mass of each blood sample was thawed for approximately 15–20 min in a water bath maintained at 37° C, and deglycerolized. Sixteen of them were resuspended in autologous plasma, and 14 were resuspended in an artificial 5 per cent albumin resuspension medium (Hyland Laboratories, Los Angeles, California) which had been stored at –20° C. The reconstituted blood was stored at 4° C for 1–17 days prior to transfusion or washing. Five lots resuspended in autologous plasma and four resuspended in the 5 per cent albumin medium were washed in the Cohn fractionator after a period of storage at 4° C (3–13 days) with 2,000 ml. of buffered isotonic saline (pH 7.2). The washed red blood cells were resuspended in the 5 per cent albumin resuspension medium and stored for either 2 h or 24 h at 4° C before transfusion. All transfusions were autologous. On

the day of transfusion, a 40–50 c.c. aliquot of each unit was transferred aseptically to a transfer pack and was incubated for 20 min at 37° C with 50–60  $\mu$ c. of radioactive disodium chromate (Squibb 'Chromotope'; Na<sub>2</sub><sup>51</sup>CrO<sub>4</sub>).

The recipient's red blood cell volume was estimated by measuring plasma volume (determined with Evans blue) and the total body haematocrit (peripheral venous haematocrit multiplied by 0.93). The red cell survival of 10 ml. of the labelled, preserved, reconstituted blood was measured. The 100 per cent survival and the apparent survival were calculated by applying Strumia's formulae<sup>9</sup>.

100 per cent survival was calculated as the total activity of the red blood cells injected (c.p.m.) divided by the total red cell volume (ml.). Apparent percentage survival was calculated as the c.p.m./ml. red blood cells in the peripheral blood divided by the 100 per cent survival value (c.p.m./ml. red blood cells) multiplied by 100.

24-h and 7-day survival values are reported. Intravascular liberation of haemoglobin associated with the removal of non-viable infused erythrocytes was evaluated by measuring plasma radioactivity 10 min after the transfusion to detect radioactivity in excess of the level estimated from the amount of radioactivity in the resuspension medium infused into the recipient's plasma volume<sup>10</sup>.

Blood from the remainder of each sample was used for the following determinations: reduced glutathione level, by Beutler's modified method using 5,5'-dithiobis-(2-nitrobenzoic acid) (DTNB)<sup>11</sup>; glutathione stability as described by Beutler<sup>6</sup> with incubation of blood at 37° for 2 h with 10 mg of acetylphenylhydrazine; glucose-6-phosphate dehydrogenase level as described by Zinkham<sup>12,13</sup>; the MCV determined by micro-haematocrits<sup>14</sup> and red blood cell counts using the Coulter counter; and the total haemoglobin measured by the cyanmethaemoglobin method<sup>15</sup>.

All samples of blood had normal glucose-6-phosphate dehydrogenase levels (mean 6.7 units/min/g Hgb, *S.D.*  $\pm$  1.5, range 4.7–12.3), reduced glutathione levels (mean 2.3 mg/g Hgb, *S.D.*  $\pm$  0.30, range 1.9–3.3), glutathione stabilities (mean 68 per cent, *S.D.*  $\pm$  10.0, range 55–85 per cent) and MCV's (mean 101  $\mu$ <sup>3</sup>, *S.D.*  $\pm$  8.0, range 83–113) on the day of collection.

Table 1 shows the MCV, reduced glutathione level, glucose-6-phosphate dehydrogenase level, and glutathione stability (all measured on the day of transfusion) and 24-h and 7-day survival of deglycerolized red blood cells resuspended initially in 5 per cent albumin medium. The length of storage of whole blood in ACD at 4° C before glycerolization, the length of storage after resuspension at 4° C prior to transfusion or washing, and the length of storage at 4° C after the washing, are shown. Reduced glutathione level, glucose-6-phosphate dehydrogenase level, and MCV were not related to the *in vivo* survival of the preserved erythrocytes.

			Range	83-110	2.3-5.0	1.9-2.7			

Fig. 1 shows that glutathione stability of approximately 40 per cent or greater is related to 24-h survival of 65 per cent or greater. Two samples of blood resuspended initially in 5 per cent albumin medium, washed after storage at 4° C for 12 or 13 days, resuspended again in 5 per cent albumin medium, and stored at 4° C for 24 h before transfusion, had 24-h chromium survival of 44 per cent and 59 per cent respectively. Both samples had nil glutathione stability. *In vivo* haemolysis (excessive plasma radioactivity 10 min after transfusion) was observed only with these two samples. Another sample in this group had glutathione stability of 25 per cent associated with a 24-h survival of 62 per cent.

Table 2 shows the same measurements for deglycerolized erythrocytes initially resuspended in autologous

plasma. All samples in this group had glutathione stability of 40 per cent or greater and 24-h survival of approximately 65 per cent or greater (Fig. 2). No excessive plasma radioactivity was noted after infusion of any of the samples in this group. Reduced glutathione level, glucose-6-phosphate dehydrogenase, and MCV were not related to *in vivo* survival in this group.

In this investigation the *in vivo* survival of deglycerolized erythrocytes was related to glutathione stability. It was noted that with a glutathione stability of approximately 40 per cent or greater, the *in vivo* survival was approximately 65 per cent or greater. The arbitrary selection of 65 per cent 24-h survival and 40 per cent glutathione stability is extremely useful in reporting the

Fig. 1. Deglycerolized erythrocytes resuspended initially in 5 per cent Hyland albumin medium; GSH stability determined on day of transfusion. ○, erythrocytes washed before transfusion; ●, erythrocytes not washed before transfusion; ▲, *in-vivo* haemolysis

Fig. 2. Deglycerolized erythrocytes resuspended initially in autologous plasma. GSH stability determined on day of transfusion. ○, Erythrocytes washed before transfusion; ●, erythrocytes not washed before transfusion

data. *In vivo* survival was unrelated to reduced glutathione level *per se*, glucose-phosphate-6-dehydrogenase level, or MCV. Two of the 30 blood samples examined showed intravascular haemolysis, and the glutathione stability in these two was nil. Both were initially reconstituted with 5 per cent albumin medium, washed after storage for 12 and 13 days at 4° C, resuspended again in 5 per cent albumin medium, and stored for approximately 24 h before transfusion. Autologous plasma as an initial resuspension medium maintained the viability and glutathione stability of the deglycerolized erythrocytes better than the 5 per cent albumin medium.

The relationship between glutathione stability and *in vivo* survival may be related to the enzyme glutathione reductase. Ebaugh *et al.*<sup>16</sup> have reported that there is a slight but definite decrease in survival of human red cells the glutathione reductase of which has been reduced to 40 per cent, and there is marked shortening of survival to 50 per cent of normal if the glutathione reductase is further reduced to levels of 10 per cent by chromate inhibition.

## SOME CHARACTERISTICS OF THE RESPIRATORY METABOLISM OF SUSPENSIONS OF RAT INTESTINAL EPITHELIAL CELLS

By DR. BABETTE K. STERN and DR. RICHARD W. REILLY\*

Department of Medicine, University of Chicago

A SIGNIFICANT gap has existed in knowledge of the function of the small intestine, because the isolated, intact, functioning, intestinal, epithelial cell had not been available for examination. This article presents the first biochemical investigation on suspensions of isolated small intestinal epithelial cells. Harrer, Stern and Reilly<sup>1</sup> recently reported a trypsin-pancreatin digest method for isolating mucosal cells which largely overcomes the problem of contamination with mesenchymal elements and microbial flora. They represent a mixture of epithelial cells from the entire rat small intestine and are suitable for *in vitro* biochemical investigations. We shall describe some characteristics of the respiration and glycolysis of suspensions of rat intestinal epithelial cells obtained by this method. In addition, measurements have been made of the invertase, lactic dehydrogenase and fructose-1,6-diphosphate aldolase activities of these cells.

Mucosal epithelial cells from the small intestine of male Sprague-Dawley rats (125–175 g) were isolated according to the procedure of Harrer *et al.*<sup>1</sup> with the following modifications. The preliminary incubation in calcium-magnesium-free Tyrode's solution was omitted. All procedures were carried out at 5°–10° C except for the 15-min incubation in trypsin-pancreatin solution (at 35° C). Following trypsinization, the enzyme solution was removed and a solution composed either of 0.2 M sucrose, 0.05 M potassium phosphate, pH 7.4, or 0.2 M sucrose, 0.05 M potassium glycylglycine, pH 7.4, was introduced into the lumen of the intestine. In some experiments various proportions of sodium ions were substituted for potassium ions. The cells were readily released into the medium by gently pressing the filled intestine with one's fingers and were collected in a syringe at the opposite end. This suspension was adjusted to give a ratio of suspending medium to trypsin-pancreatin of 7:1. The cells were collected by centrifugation at 500g for 5 min and washed twice in the suspending medium. Alternatively, the trypsin-pancreatin solution was discarded and cells were collected in the

suspending medium by centrifugation and washed once. They were re-suspended each time in the media by repeated flushing through a 14-gauge needle. Oxygen uptake was measured at 30° C, in 100 per cent oxygen unless otherwise indicated. Warburg vessels, in which the usual centre well was replaced by a trough fused to the wall of the main compartment and connected with one side-arm<sup>2</sup>, were used. The trough contained 0.5 ml. of 20 per cent potassium hydroxide. Equal amounts of the cell suspension were added to the Warburg vessels for each experiment. The vessels were equilibrated for 10 min. The amount of cell protein added varied from 3 to 19 mg per vessel in different experiments. The rate of respiration and glycolysis was independent of cell concentration in this range. It took 80–90 min from the time the experiment was initiated until the cells were placed in Warburg vessels. The cell metabolism is expressed according to the following quotients:  $Q_{O_2}$  =  $\mu$ l. O<sub>2</sub> uptake/mg protein/h in oxygen;  $Q_L$  =  $\mu$ l. lactic acid produced/mg protein/h in oxygen;  $Q_L^A$  =  $\mu$ l./mg protein/h in argon. Protein was determined by the method of Lowry *et al.*<sup>3</sup> on aliquots of cell suspensions. Lactic acid was determined by the method of Barker and Summerson<sup>4</sup>. The values given in the table were corrected for both the initial lactic acid content of the cells and that produced during the 10-min temperature equilibration in the Warburg vessel. Lactic dehydrogenase was determined on aliquots of the cell suspension by the method of Kornberg<sup>5</sup>. Glucose formed by the action of invertase on sucrose was determined with a special glucostat reagent (Worthington Biochemicals Corporation). Values were always corrected for the initial glucose content of the cell suspension. Fructose-1,6-diphosphate aldolase was determined by the method of Peansky and Lardy<sup>6</sup> on aliquots of cells suspended in 0.2 M sucrose, 0.05 M potassium glycylglycine, pH 7.4, with appropriate blanks.

Cell counts were taken for every experiment and the viability determined by the Nigrosin staining technique<sup>7</sup>. The viability of the cells immediately before respiration

\* U.S. Public Health Research Fellow (N.C.I.).

measurements ranged from 55 to 90 per cent, while at the end of 1 h at 30° the viability of the cells ranged from 45 to 60 per cent. The cells were morphologically normal when stained with haematoxylin and eosin. Two types of epithelial cells were distinguished: a large columnar or slightly rounded cell with brush border, and a smaller rounded form seen individually or within isolated crypts. Differential counts revealed that about 81 per cent of the cells were intact epithelial cells, 13 per cent of the cells were lymphocytes and granulocytes and 6 per cent were naked nuclei. Since the lymphocytes and granulocytes were about 1/5 the size of the epithelial cells, their contribution to the experiments reported here would not be significant. Cells which were suspended in sucrose phosphate medium were examined under the electron microscope by Dr. Charles Johnson and appeared morphologically intact. The mitochondria appeared normal, but the cytoplasm contained some fat droplets. No bacteria were visible and bacterial colony counts showed negligible contamination.

Table 1. EFFECT OF VARIOUS SUBSTRATES ON THE RESPIRATION OF INTESTINAL EPITHELIAL CELLS WASHED AND SUSPENDED IN A BUFFERED SUCROSE MEDIUM

Exp. No.	Additions	Q <sub>O<sub>2</sub></sub>
1	None	-5.0
	Pyruvate $9.5 \times 10^{-3}$ M	-6.1
	Succinate $9.5 \times 10^{-3}$ M	-7.4
2	None	-4.4
	Lactate $9.5 \times 10^{-3}$ M	-5.3
	Fumarate $9.5 \times 10^{-3}$ M	-6.2
	Citrate $9.5 \times 10^{-3}$ M	-4.9
3	None	-5.9
	Succinate $9.5 \times 10^{-3}$ M	-10.0

Exps. 1 and 2. Warburg vessels contained cells (equivalent to 19 mg of cell protein in Exp. 1 and 10.5 mg of cell protein in Exp. 2) suspended in 0.2 M sucrose, 0.05 M potassium phosphate, pH 7.4 (final potassium concentration = 0.095 M) and 142 units each, of penicillin and streptomycin in a final volume of 1.05 ml. The substrates were added as their potassium salts, pH 7.0, and a comparable amount of KCl was added to the control vessel.

Exp. 3. Warburg vessels contained cells (equivalent to 11.3 mg of cell protein) suspended in 0.2 M sucrose, 0.05 M glycylglycine, 0.047 M potassium ion, pH 7.4 and 142 units each, of penicillin and streptomycin in a final volume of 1.05 ml.

Results presented in Table 1 indicated that intestinal epithelial cells from the rat respired after being washed and suspended in a 0.2 M sucrose medium buffered with either potassium phosphate or potassium glycylglycine. Enzymatic hydrolysis of sucrose by epithelial cell invertase provided glucose as an energy source. Oxygen consumption was usually linear for 40 min and in some experiments for 60 min. Respiration was stimulated when succinate, pyruvate, citrate, fumarate and lactate were added. The addition of 0.002 M DPN, ADP and MgCl<sub>2</sub> alone or in combination had no effect, indicating that these co-factors were not rate-limiting or lost during cell isolation. Added glucose, glutamate, acetate or CaCl<sub>2</sub> did not affect respiration.

It should be emphasized that the 0.2 M sucrose, 0.05 M potassium phosphate solution was employed for isolation and washing of cells because, in our experience, this medium proved to be best for obtaining intact, viable cells. However, we were interested in examining the effects of lower sucrose concentrations on respiration and glycolysis. It was necessary to reduce the sucrose concentration after the cells were isolated. This was accomplished by diluting the cells out in the Warburg vessel to a final concentration of 0.05 M sucrose, 0.05 M potassium phosphate, pH 7.4, producing a cell lysate. These cells were fragmented when observed under the microscope. The results are not given, but this cell lysate respired as well and produced as much lactic acid as intact cells. Berry<sup>8</sup> found that suspensions of cells from mouse liver isolated in 0.3 M or 0.4 M sucrose respired in a simple buffered medium containing 0.06–0.2 M sucrose. Liver cells oxidized citric acid cycle intermediates, but carbohydrate substrates did not stimulate oxygen uptake owing to the loss of glycolytic enzymes from the liver cells during isolation. Results will be presented later to show that intestinal epithelial cells retain their glycolytic enzymes. Berry<sup>8</sup>, Zimmerman *et al.*<sup>9</sup>, Kalant and Young<sup>10</sup> and Laws and Stickland<sup>11</sup>

Cells were isolated and suspended in 0.2 M sucrose, 0.05 M phosphate, pH 7.4, adjusted to the potassium and sodium ion concentration as shown in the table. All solutions contained penicillin and streptomycin as indicated in Table 1. Samples of cell suspensions containing 9–16 mg of cell protein were added to Warburg vessels.

have reported that suspensions of isolated liver and kidney cells do not respire in Krebs's phosphate-saline with or without glucose, but will respire if succinate is present. The respiration of intestinal epithelial cells in Krebs's phosphate-saline-glucose varied considerably from experiment to experiment. In some experiments rates as high as 15  $\mu$ l./oxygen uptake/mg protein/h were obtained, whereas in other experiments there was little or no oxygen consumption. Since consistent results could be obtained in the buffered sucrose medium, experiments reported here were all carried out with cells isolated and suspended in sucrose.

The effect of substituting sodium ions for potassium ions in the sucrose-phosphate isolation and suspending medium was investigated and the results are shown in Table 2. Cells isolated in sucrose sodium phosphate were morphologically normal and the viability was as high as cells isolated in sucrose potassium phosphate. However, cellular respiration and glycolysis were very low when potassium ions were replaced by sodium ions and could not be augmented by adding potassium ions to the reaction mixture in the Warburg vessel. If potassium ions were present in the isolation medium, the rate of oxygen consumption and lactic acid formation increased. The data show that oxygen consumption rose as the potassium ion concentration was increased to 0.019 M, and then, at higher potassium ion concentrations, declined somewhat. Added sodium ions were not necessary for respiration or glycolysis. The results are not given, but the cells responded in a similar manner when sucrose sodium glycylglycine instead of sucrose potassium glycylglycine were used for cell isolation and suspension. The presence of potassium ions in the isolation and suspending medium is essential for the maintenance of cellular function as measured by respiration and glycolysis.

One of the most striking features of the carbohydrate metabolism of intestinal mucosa is its high aerobic and anaerobic glycolysis. The relationship between respiration and glycolysis of intestinal epithelial cell suspensions is given in Table 3. The rate of aerobic and anaerobic glycolysis is very high. There was an increase in lactic acid production in the absence of oxygen (Pasteur effect). Wilson and Wiseman<sup>12</sup>, using everted sacs of rat intestine, found an appreciable Pasteur effect only in the lower half of the rat intestine. Inasmuch as cell suspensions used in experiments reported here represent a mixture of cells from various levels of the rat intestine, no conclusions can be drawn in regard to a possible Pasteur effect in the jejunum.

Table 3. OXYGEN CONSUMPTION AND AEROBIC AND ANAEROBIC LACTIC ACID PRODUCTION OF INTESTINAL EPITHELIAL CELLS IN SUCROSE PHOSPHATE MEDIUM

Exp. No.	Q <sub>O<sub>2</sub></sub>	Q <sub>L</sub>	Q <sub>L'</sub>
1	-4.7	7.5	10.2
2	-6.1	8.5	14.1
3	-4.0	6.7	9.9

Warburg vessels contained cells (equivalent to 3.0, 14.8 and 15.3 mg of cell protein in Exps. 1, 2 and 3 respectively) suspended in sucrose phosphate medium, pH 7.4. The composition of the medium was identical with that used in Exps. 1 and 2 of Table 1.

**Table 4. EFFECT OF IODOACETATE ON OXYGEN CONSUMPTION AND LACTIC ACID PRODUCTION BY INTESTINAL EPITHELIAL CELLS**

Exp. No.	Experimental conditions	QO <sub>2</sub>	QL
1	No additions	-3.9	6.0
	Iodoacetate $5 \times 10^{-5}$ M	-2.6	3.0
	Iodoacetate $5 \times 10^{-4}$ M	-1.9	0.4
	Iodoacetate $5 \times 10^{-3}$ M	-1.5	0.3
2	No additions	-3.8	5.4
	Iodoacetate $5 \times 10^{-4}$ M	-1.8	1.5
	Iodoacetate $5 \times 10^{-3}$ M	-1.9	0

Warburg vessels contained cells (equivalent to 11.5 mg of cell protein in Exp. 1 and 16.0 mg of cell protein in Exp. 2) suspended in sucrose potassium phosphate buffer, pH 7.4. The composition of the medium was identical with that used in Exps. 1 and 2 of Table 1.

The effect of iodoacetate on respiration and glycolysis of intestinal epithelial cells is shown in Table 4. Lactic acid production was virtually abolished in the presence of  $5 \times 10^{-3}$  M iodoacetate. Oxygen consumption was decreased to about 50 per cent of the control value, indicating that either the cells accumulated enough substrates to sustain respiration or that they utilized pathways other than the Embden-Meyerhof for channeling metabolites into the tricarboxylic acid cycle and electron transport chain.

**TABLE 5. INVERTASE, LACTIC DEHYDROGENASE AND ALDOLASE ACTIVITIES OF INTESTINAL EPITHELIAL CELLS**

Invertase ( $\mu$ moles of sucrose hydrolysed/mg protein/h)	3.2, 3.7, 4.1, 7.5
Lactic dehydrogenase ( $\mu$ moles lactate formed/mg protein/min)	0.5, 0.7, 1.0, 1.5
Fructose-1,6-diphosphate aldolase ( $\mu$ moles of fructose-1,6-diphosphate split/mg protein/5 min)	0.13, 0.14, 0.23, 0.35

Each of the above figures represents an enzyme determination on an aliquot of cell suspension obtained from a different rat. Assays were carried out as described in the text.

In Table 5 the activities of invertase, lactic dehydrogenase, and aldolase in isolated suspensions of intestinal epithelial cells are shown. Each value represents a determination on cells from a different rat. There was a considerable range in the specific activity of these enzymes. This is as expected, since there are gradations in enzyme activities along the intestine and in separate experiments various proportions of cells from different regions of the small intestine are obtained. Invertase was measured as the amount of sucrose hydrolysed in 1 h under the same experimental conditions as oxygen uptake measurements. Iodoacetate was added to prevent glucose utilization by the Embden-Meyerhof pathway. The presence of invertase in the isolated epithelial cells confirms the work of Miller and Crane<sup>13</sup>. The amount of cell protein present in the respiration experiments with sucrose phosphate was 3-19 mg/200  $\mu$ moles sucrose. If one takes an average value of 4.6  $\mu$ moles of sucrose hydrolysed/h/mg protein, then 13.8-87  $\mu$ moles of glucose were produced during

1 h at 30°. The concomitant decrease in the sucrose concentration over a 1-h period did not affect respiration or lactic acid production as indicated earlier in the experiments where a cell lysate was prepared by diluting out the cells in the Warburg vessel to a final concentration of 0.05 M sucrose 0.05 M potassium phosphate. Aliquots of cell suspensions were sonated before measuring lactic dehydrogenase and aldolase. The activities of both fructose-1,6-diphosphate aldolase and lactic dehydrogenase indicate that these enzymes were present in sufficient concentration to account for the amount of lactic acid produced by these cells. Lactic dehydrogenase was assayed by measuring the oxidation of DPNH by pyruvate in the presence of the epithelial cell homogenates. There was no DPNH oxidase activity in the absence of pyruvate. This confirms the work of others<sup>14</sup> that mitochondria from mammalian tissues, when undamaged by preparative techniques, are unable to oxidize extramitochondrial DPNH, presumably because of the impermeability of the mitochondrial membrane to the reduced pyridine nucleotide. Berry<sup>5</sup> has reported that liver cells lose most of their aldolase and lactic dehydrogenase during isolation and washing. Though no attempt was made to measure the amounts of enzymes lost in washing, it is clear that intestinal epithelial cells which have been washed extensively possess a sufficient complement of at least two enzymes of the Embden-Meyerhof pathway to carry out a vigorous glycolysis.

Data reported here represent the first biochemical investigations of suspensions of isolated, intestinal epithelial cells and support the concept of the dissociated intestinal epithelial cell as an intact functioning unit which is appropriate for investigation of problems peculiar to the cellular level of intestinal function.

## IMMUNOSEDIMENTATION: A BI-DIMENSIONAL AGAR-GEL PLATE TECHNIQUE FOR ANTIGEN ANALYSIS

By PROF. FÉLIX CÓRDOBA, CONCEPCIÓN GONZÁLEZ and PABLO RIVERA

Departamento de Bioquímica, Facultad de Medicina, Universidad Nacional Autónoma de México, México 20, D.F.

THE adaptation of sucrose gradients for examining sedimentation behaviour of enzymes, developed by Martin and Ames<sup>1</sup>, can be used advantageously for the separation of antigens in a mixture as in whole human serum. The distribution concentration of antigens down the centrifuge tube can be obtained by protein measurements of the separated fractions, but the overlap of the proteins excludes the possibility of attaining sedimentation coefficients from serum components, with the exception of albumin normally present in sufficient amount to produce a distinct peak.

Because centrifugation of protein mixtures in gradients with subsequent analysis of human serum fractions by a series of agar double diffusion gel tests against rabbit anti-human serum did not improve the resolution of antigens, we decided to combine electrophoretic separation, across the sedimentation axis in the agar plate, as a second step before developing the antigens with the antiserum.

As at present used, the technique consists of overlaying 0.1-0.2 ml. of undiluted human serum, or another protein solution or mixture for which there is available a potent precipitating antiserum, on top of a sucrose gradient

established in a cellulose nitrate centrifuge tube (12 × 50 mm) for the swinging bucket rotor, *SW 39 L*, of the Spinco model *L* preparative ultracentrifuge. A useful gradient for normal human serum, with a calibrated scale of 0–13S (Svedberg units), was obtained with 9–24 per cent sucrose solutions centrifuged for 18 h at 100,000*g* and 4° C. In serum analyses 0.9 per cent sodium chloride was used for preparing the sucrose gradients.

Fig. 1. Photograph of a normal human serum sample analysed by immunosedimentation with rabbit anti-human serum. Precipitates were stained with amido black<sup>3</sup>. Positive side is to the right. The elongated spot to the anodic side is serum albumin specific precipitate. The round spot to the left is due to 7S  $\gamma$ -globulins precipitate. Outermost edge of the spot corresponds to 7S value in the vertical co-ordinate. The diagram below was drawn directly from the agar plate, under a photographic amplifier. Albumin and  $\gamma$ -globulin spots were identified in control runs with the pure proteins,  $\alpha_2$ -lipoproteins by lipid staining with oil red<sup>2</sup>. The names of the rest of the antigens shown in the diagram were placed in the expected position, for these antigens, in immunoelectrophoresis. Note the relative place and shape of the spots in the 0–13S sucrose gradient. The diagram at the top is from the immunoelectrophoretic analysis of the same normal human serum sample developed with the same rabbit antiserum.

At the end of the run the centrifuge tubes were removed from the rotor, fixed to a stand, and pierced at the bottom with a hypodermic needle to collect, into 25 small test-tubes, consecutive volumes of the spun-down solution from the centrifuge tube. Each of the 25 aliquots contained mixtures, in various proportions, of the antigens in human serum separated in accordance with sedimentation coefficients<sup>1</sup>.

The electrophoresis step was performed on an agar plate filled with 18 ml. of 1.5 per cent agar Difco 'Noble' in Aronson's buffer<sup>2</sup>, of 60.5 g *tris*, 6.0 g EDTA and 4.6 g boric acid per litre, at pH 8.7. The melted agar was poured into trays constructed with 7 cm × 7 cm glass plates with glass rods glued to the edges. At the centre of the plate 25 small round holes were implemented with punches fixed, at 1-mm intervals, to an acrylic square-shape block. These perforations were filled with about 20  $\mu$ l. of each of the solutions of antigens in the 25 test-tubes. The electrical connexions were secured to the plates with thick, wet paper wicks, and a potential of 120 V was supplemented, from a regulated power supply, for 2 h at room temperature. When the electrophoretic run was terminated the current was turned off and the agar plates were overflowed with rabbit antiserum, prepared against pooled human serum, and placed inside a humid chamber awaiting the development of the 'spots' of specific precipitate to appear. Albumin spot was visible in a few hours and the rest of the antigens of human serum were clear in 48 h. The excess antiserum was poured off and the plates washed exhaustively with pH 8.6 borate buffer 0.1 M for at least 3 days and with several rinses of running tap-water afterwards. Finally, they were dried, as immunoelectrophoresis plates, with filter paper, and stained with amido black for proteins and oil red in 60 per cent ethanolic solution for lipids<sup>3</sup>.

Fig. 1 shows a photograph of a sample of normal human serum developed by immunosedimentation. The accompanying diagram was outlined after the original plate. A diagram of a control immunoelectrophoresis run, of the same human serum sample under the same experimental conditions and developed with the same antiserum, is shown on top. The presence of a particular spot is due to the precipitation of antibody by the antigen in the agar plate, exactly as in the method of 'direct immunoelectrophoresis' recently described<sup>4</sup>.

In the plate (Fig. 1), the horizontal axis corresponds to electrophoretic mobilities with the anodic side to the right. The vertical axis, along the sequence of the 25 symmetrically dispersed perforations containing the various antigen mixtures, can be visualized as a sedimentation constant axis (Svedberg units). The calibration of this parameter was established, in the same experiment, with a centrifuge tube containing 4 mg of twice crystallized human albumin and analysis of the protein by Folin's reagent<sup>5</sup>, in each of the solutions in the 25 test-tubes.

There are several features which distinguish this technique from previous ones which in our view are of some relevance. First, the possibility of appraising approximate sedimentation coefficients of some antigens, that is, albumin, 7S  $\gamma$ -globulin, macroglobulin, in serum samples, simultaneously with their electrophoretic localization and serological reactivity with a particular antiserum, seems interesting; and, secondly, the visual overall picture of a family of 'spots' of immunosedimentation runs, with human sera, can be of practical application.

Another interesting feature worth mentioning is that some antigens, albumin for example, appear in the plate as a regular elongated spot and not as a number of discrete spots that one would expect from multiple circular sources. This coalescence is due to the diffusion rate of albumin and other proteins, like 7S  $\gamma$ -globulins, during the lapse of the electrophoretic migration.  $\alpha_2$ -Lipoproteins that were identified with oil red and are shown in the diagram produce, due to their much slower diffusion

rate, a number of spots corresponding each to a place in the gradient in which they are located at the end of the run.

The outermost edge of each spot should correspond to maximum antigen concentration, to the peak, and to the sedimentation coefficient when this point is moved, horizontally, to the Svedberg units axis<sup>1</sup>. The estimation of this point is feasible for some antigens; the outer edge of the  $\gamma$ -globulin spot is at the 7S mark and the one of albumin close to the 4.5S, both values in close agreement to the ones in the literature<sup>6</sup>. It is evident that this simple procedure cannot be employed, with accuracy, with most of the revealed antigens because they are too close together to give sharp contours. A few other antigens, nevertheless, are present in their expected positions;  $\alpha_2$ -macroglobulin comes to the bottom of the tube, off the scale of 13S of this particular gradient, and is easily

distinguished in the photograph. Other proteins shown in the diagram were named, in spite of the fact that they have not been unquestionably identified, as a reference for the approximate site of these antigens in immunosedimentation.

A protein in a mixture, analysed bi-dimensionally as already described here, can be detected by different means instead of antiserum. Thus, an enzyme in a crude extract can be detected by adding the appropriate substrates and couplers to give a non-diffusible coloured spot.

## HAEMOGLOBIN SYNTHESIS AND POLYSOMES IN INTACT RETICULOCYTES

By DR. GEORG R. PHILIPPS

Division of Biology, California Institute of Technology, Pasadena, California

THE active units in protein synthesis are the polysomes<sup>1-3</sup>—structures consisting of clusters of ribosomes held together by a single-stranded messenger RNA molecule<sup>4</sup>. As shown by electron microscopy, the principal component in reticulocytes is the penta-ribosome<sup>5,6</sup>. Investigations with isolated polysomes have indicated that probably the attachment of monosomes at one end of the mRNA initiates peptide formation<sup>7,8</sup>. In the present concept of polysome function<sup>2,9</sup> the polypeptide chain grows as the ribosome moves along the mRNA, and becomes detached at the other end with the completion of the chain. This orderly breakdown of polysomes *in vitro* and its dependence on protein synthesis have been demonstrated in reticulocytes<sup>10</sup>, rat liver<sup>11</sup>, and HeLa cells<sup>7</sup>. While in the cell-free system the incorporation of amino-acids into ribosomes normally ceases after 30 min<sup>12</sup>, intact reticulocytes synthesize haemoglobin for several hours at a nearly linear rate<sup>13</sup>. Examining the *in vitro* maturation of reticulocytes, Marks *et al.*<sup>14</sup> observed that as reticulocytes mature the activity of the polysomes declines while their concentration in the cell decreases, but to a lesser extent. This suggests that polysomes may become partially inactive while remaining polysomes. Glowacki and Millette<sup>15</sup> came to a similar conclusion examining reticulocytes separated according to their state of maturation on a bovine serum albumin gradient. Evidence is presented here that under certain conditions the activity of polysomes in reticulocytes decreases drastically while there is actually no decrease in the ribosomes sedimenting as polysomes.

Reticulocytosis was induced in female rabbits, weighing between 3.0 and 3.5 kg, by six daily subcutaneous injections of 2.5 per cent neutralized phenylhydrazine solution (0.25 ml./kg). Approximately 80 ml. blood was obtained on the 7th day from each animal by heart puncture and heparin was added immediately to give a final concentration of 0.08 per cent. The reticulocyte count was between 65 and 85 per cent. The cells were collected by centrifugation at 4,000 r.p.m. for 5 min and washed with NKM (0.153 M NaCl, 0.005 M KCl, 0.005 M MgCl<sub>2</sub>). Ten ml. of packed cells were incubated with 20 ml. of anaemic plasma and 20 ml. of a reagent mixture, containing in a total volume of 500 ml.: 50 ml. Earle's solution, Spinner, 10×; 100 ml. of an amino-acid mixture; 5-ml. vitamin solution (Eagle), 100×; 400 units penicillin G and 2 mg streptomycin. The concentration in the reagent mixture

of MgSO<sub>4</sub> was brought to 1.2 mM and NaHCO<sub>3</sub> (40 mM) was added. The pH of the incubation mixture was 7.5 at 37° C under 95 per cent oxygen: 5 per cent carbon dioxide. Two milligrams of ferrous ammonium sulphate and 12.75  $\mu$ moles L-leucine-<sup>14</sup>C (uniformly labelled), spec. activity 2.5 to 3.0 mc./mmole, were added. The amino-acid mixture contained (mmoles/l.): L-alanine, 1; L-arginine, 2; L-asparagine, 1; glycine, 2; L-histidine, 5; L-isoleucine, 2; L-lysine, 5; L-methionine, 1; L-phenylalanine, 4; L-proline, 2; L-serine, 2; L-threonine, 2; L-tryptophan, 1; L-tyrosine, 2.5; L-valine, 8; L-cysteine, 1.0; L-glutamine was added separately corresponding to 4.0 mM in the reagent mixture. All incubations were made under 95 per cent oxygen: 5 per cent carbon dioxide at 37° in a water-bath shaker.

At the end of the incubation the cells were collected by centrifugation at 4,000 r.p.m. and washed twice with NKM. They were then 'shock-lysed' according to Marks *et al.*<sup>14</sup>. Ribosomes were prepared by layering the haemolysate in Spinco rotor 30 tubes on 3 ml. of STM (0.5 M sucrose, 0.01 M tris pH 7.1, 0.0015 M MgCl<sub>2</sub>, 0.04 M KCl) and centrifugation at 78,000g for 3 h. The ribosomal pellet was suspended in 1/8 original volume of Solution F<sub>2</sub> (0.01 M tris pH 7.1, 0.0015 M MgCl<sub>2</sub>, 0.04 M KCl) using a loose-fitting homogenizer, and centrifuged in rotor 40 tubes through 5 ml. of STM for 5 h. The concentration of ribosomes was determined using an extinction coefficient at 260 m $\mu$  (25° C) of 11.2/mg/ml. (ref. 17) and as molecular weight  $4.1 \times 10^6$  (ref. 18). 0.5 mg samples were precipitated with 10 per cent cold TCA. After 1 h the precipitate was collected on 'Millipore' filters (0.45  $\mu$  pore size) which were dried, glued on aluminium planchets, and counted in a Nuclear Chicago low-background gas-flow counter.

For sucrose gradient analyses ribosomes centrifuged once through STM were gently suspended in Solution F<sub>2</sub> using a glass rod instead of a homogenizer. One millilitre of this suspension was layered on to a linear sucrose gradient of 30–15 per cent sucrose w/v in Solution F<sub>2</sub> and centrifuged in a SW 25 rotor at 4° C. Usually fractions of 0.60–0.75 ml. were collected and analysed as described elsewhere<sup>19</sup>.

L-Leucine-<sup>14</sup>C was obtained from New England Nuclear. The constituents for the reagent mixture were from Hyland Laboratories, Los Angeles. All preparations were made at 4° C.

Fig. 1. Sucrose gradients of polysomes after whole cell incubation with L-leucine- $^{14}\text{C}$  in the presence of 11.2 mM glucose (Exp. 4, Table 2). 1 ml. of ribosome suspension was layered on 26 ml. of a 30–15 per cent sucrose gradient and centrifuged for 3 h in a *SV* 25 rotor (—). (a) Polysomes obtained after 15 min incubation; (b) after 120 min incubation

These investigations were aimed at establishing an optimal system for *in vitro* incubation of reticulocytes, which would permit the cells to synthesize proteins at an even rate for several hours. As a criterion for the activity of the cells the radioactivity incorporated into ribosomes was taken. Ribosomes, prepared as already described here, do not retain any haemoglobin, as shown by spectrophotometry. No absorbancy at 418 mμ was found if the ribosomes were centrifuged twice through *STM*, while some absorbancy was still present if the ribosomes were centrifuged twice for the same length of time but using *STM* only in the second centrifugation. This, and the fact that ribosomal protein is not synthesized in reticulocytes<sup>19</sup>, enabled us to associate all label on the ribosomes with the growing peptide chain. The incorporation of amino-acids into polysomes and, for comparison, into soluble proteins was followed for various times of incubation. Using an incubation medium similar to that described previously<sup>20</sup>, it was found that ribosomes lose some of their initial activity during a 90-min incubation period. Sucrose gradient analyses of ribosomes obtained after 15 min and 90 min (120 min) of incubation indicated no breakdown of polysomes but rather a decrease in their specific activity.

To establish if the state of reticulocytosis reflects in any way the ribosomal activity in these cells, rabbits were injected with phenylhydrazine for various lengths of time. As can be seen in Table 1, the reticulocyte count

does not reflect the 'average activity' of the ribosomes. If the rabbits were rested for one day after the last injection, the specific activity of the ribosomes was usually slightly higher after 15 min but decreased faster during the 2-h incubation period. Since it appears that two classes of reticulocytes exist, one with a life-span of 17 days, the other with a much shorter life-span of 2 days<sup>21</sup>, this has to be taken into account in interpreting my results. The differences are small, however. In those animals which were injected for a longer period of time the peripheral blood contains more reticulocytes, as well as cells which are more mature. In these experiments, plasma and cells were obtained from the same animal. I examined the possibility that a factor in the plasma might be responsible for the decrease in cell activity during the incubation. The substitution of anaemic plasma obtained from normal animals had very little effect on the ribosomal activity. Treatment of plasma with bentonite, known to absorb RNases, did not increase the capacity of the cells to synthesize proteins, either during 15 min or 120 min of incubation. It seems unlikely, therefore, that RNases present in the plasma enter the cells under conditions adopted here.

The general requirements for *in vitro* incubation of reticulocytes had been examined by Borsook *et al.*<sup>13</sup>, using the incorporation of label into soluble proteins as the criterion of cell activity. Approximately 90 per cent of all soluble proteins in reticulocytes represent haemoglobin, while the remainder constitute a variety of non-haem proteins. At least part of these are synthesized at a much faster rate (Philipps, G. R., unpublished results). However, since the incorporation of amino-acids into nascent protein reflects more accurately the activity of the cells, several aspects of the system were reinvestigated. A high concentration of plasma in the incubation mixture retained the activity of the cells longer. The concentration of electrolytes in the reagent mixture is approximately the same as in the plasma. A high concentration of amino-acids and iron, as compared with the plasma concentration<sup>23</sup>, is necessary to guarantee a continuous protein synthesis for 2 h (Table 2, Exps. 1–3). By increasing the glucose concentration the activity of the cells increased

Table 1. HAEMOGLOBIN SYNTHESIS AND THE STATE OF RETICULOCYTOSIS

No. of days injected	Per cent reticulo-cytes	15-min incubation		120-min incubation	
		Specific activity: (c.p.m./O.D. <sub>260</sub> )		Specific activity: (c.p.m./O.D. <sub>260</sub> )	
		Ribosomes	Soluble proteins	Ribosomes	Soluble proteins
7*	77	43.0	257	25.4	604
7	90	41.2	280	28.6	799
6*	76	45.6	323	30.5	914
6	89	43.3	424	34.5	1,068
5*	85	43.4	232	26.7	647
5	74	46.9	413	30.7	974

Rabbits were injected for the indicated number of days; an asterisk means that these animals rested one day after the last injection before the blood was collected. 20 ml. of cells were incubated with 40 ml. of reagent mixture<sup>20</sup> containing 11.2 mM glucose and 5 ml. of normal plasma. 0.04 mc. algal protein hydrolysate, diluted with the amino-acid mixture, was added to 20 ml. of cells. Ribosomes were prepared as described in the text; the soluble proteins were obtained from the supernatant of the last ultracentrifugation and dialysed for 24 h. Each value represents the mean of two experiments.

Table 2. INCORPORATION OF LEUCINE INTO RIBOSOMES AND SOLUBLE PROTEINS

Exp.	Concentration in the reagent mixture*				$\frac{\mu\text{moles leucine}^\dagger}{\mu\text{moles ribosomes}}$		Decrease in ribosomal activity (%)	$\frac{10^{-4} \mu\text{moles leucine}}{\text{O.D.}_{260} \text{ soluble proteins}}$	
	L-leucine (mM)	Amino-acids (mL/100)	Glucose (mM)	Iron (mM)	15 min	120 min		15 min	120 min
1	0.54	10	5.6	0.06	4.85	3.42	29	4.24	24.95
2	1.04	20	5.6	0.06	5.09	4.20	17	8.18	38.97
3	1.04	20	5.6	0.25	6.86	6.67	3	15.52	52.05
4	0.54	10	11.2	0.06	5.06	2.81	44	8.45	37.90
5	0.54	20	11.2	0.25	6.24	3.51	56	13.20	41.38

\* The reagent mixture was diluted 2/5 in the incubation mixture. Due to this dilution, the actual concentration of amino-acids and iron is smaller; the glucose concentration is approximately the same in the incubation mixture.

† These values were corrected for the decrease of the specific activity of leucine due to the intracellular pool in reticulocytes ( $0.25 \text{ mM}$ )<sup>22</sup> and the amount present in plasma ( $0.4 \text{ mg per cent}$ )<sup>23</sup>. The actual values were 18 and 22 per cent smaller, respectively.

when used in a medium which is sub-optimal with respect to the concentration of amino-acids and iron (Table 2, Exps. 2 and 4), otherwise the glucose effect is negligible. The glucose concentration in the whole blood is approximately 5 mM, which corresponds to the concentration used in Exps. 1-3. At a high glucose concentration (Exps. 4 and 5) the activity of ribosomes decreases rapidly as compared with the two incubation periods.

This 'glucose effect' was examined in more detail using sucrose gradient analyses of the polysomes (Fig. 1). The distribution of a 15-min incubation is plotted in Fig. 1a. As expected, the radioactivity overlaps with the absorption peak characteristic for polysomes, while a small number of counts found in the 80S ribosome peak are probably due to polysomes disrupted during the prepara-

tion. Fig. 1b depicts the situation after a 120-min incubation. The major part of the activity is still found associated with the polysomes; however, the specific activity is much less than after 15 min of incubation. This is more clearly illustrated in Fig. 2. The specific activity of the polysomes and monosomes is compared for a 15-min and a 120-min incubation. Using a glucose concentration of 5.6 mM, the specific activity is highest in the region of the heaviest polysomes, reaching a minimum at the 80S ribosomes. After 2 h of incubation, the slope of the curve has not changed essentially, but a small shift of the activity towards the lighter polysomes is apparent (Fig. 2a). The situation is very different if a glucose concentration of 11.2 mM in the incubation medium is used (Fig. 2b). A much greater loss of specific activity is found after 2 h. The decrease is most in the heavier polysomes and somewhat less in those which sediment in the middle of the gradient. At either glucose concentration a minimum of activity is associated with the monomer fraction. The relative amount of polysomes, compared to the monosome fraction, did not change greatly, but a shift towards the fractions containing the heavier polysomes appeared (Fig. 3). This increase of the amount of polysomes sedimenting with a high *S* value after prolonged incubation, though not great, was found in several experiments. As I shall describe elsewhere<sup>19</sup>, ribosomes do not easily aggregate under these experimental conditions. In a similar experiment, I compared the total amount of ribosomes after 15 min and 120 min of incubation. Starting with exactly 5 ml. cells, I recovered in a duplicate experiment 5.6 and 5.5 mg ribosomes after 15 min and 5.0 mg after 120 min. A probable explanation of these results is a gradual degradation of polysomes to ribosomes and the formation of ribosomal sub-units and smaller degradation products. The heavier polysomes, most active in protein synthesis, would be more stable than the lighter ones.

It has been shown here that by using the proper conditions for the incubation of reticulocytes, the polysomes preserve their activity throughout a 2-h incubation.

Fig. 2. Specific activity of ribosomes centrifuged through a sucrose gradient. Polysomes were analysed as described in Fig. 1 and the incorporation of moles leucine per mole ribosome plotted against the fraction number. (a) Incubation in 5.6 mM glucose (Exp. 2, Table 2); (b) incubation in 11.2 mM glucose (Exp. 4, Table 2). —●—, 15-min incubation; —○—, 120-min incubation. (The total fractions collected in (a) and (b) were somewhat different, which explains the different position of the 80S peak in both graphs)

Fig. 3. Centrifugation of ribosomes in a sucrose gradient. Polysomes were analysed as described in Fig. 1 and the absorbance at 260 mμ plotted against the fraction number. Experimental conditions as described in Exp. 4, Table 2. —●—, 15-min incubation; —○—, 120-min incubation

Disregarding the fact that a small percentage of the newly synthesized proteins are not haemoglobin, it can be calculated that approximately 80 per cent of all polysomes are active in the synthesis, if there are 17.5 leucine residues per globin chain. These numbers are somewhat smaller than those published by Rich *et al.*<sup>22</sup>. The stimulating effect of iron and glucose has been described<sup>13</sup>. However, taking the labelling of the polysomes as a criterion for the activity of the cells, the stimulation at a high glucose concentration is only transitory and the activity of the polysomes decreases during two hours of incubation. The results suggest that this glucose effect is different from the stimulation by other substances. At the present time I cannot offer an explanation for this observation. The fact, however, that it is possible to depress the synthesis of proteins while preserving the polysomal structure raises some questions.

It has been shown in cell-free experiments that polysomes break down during protein synthesis and that as incubation proceeds the activity in the polysome peak gradually disappears and shifts to smaller units. Simultaneously the activity of the 80S ribosomes increases<sup>7,10</sup>. The limiting factor for the synthesis of proteins is, under these conditions, the re-attachment of the monosomes to the polysome cluster. My results indicate that during protein synthesis in whole cells no breakdown of polysomes takes place. A slight increase in polysomes sedimenting with a higher *S* value was found not only under conditions of reduced protein synthesis (Fig. 3) but also when the synthesis proceeds at a nearly equal rate. The relative activity of the polysomes after 2 h of incubation was somewhat displaced towards smaller structures, but the activity of the 80S fraction always showed a minimum.

The present theory of polysomal function in a monocistronic system, as assumed for the haemoglobin synthesizing apparatus, correlates the length of the prospective peptide chain and the length of the mRNA strand. At least 60 per cent of all polysomes appear in clusters of five or four ribosomes in electron micrographs<sup>8,24</sup>, and the length of the expected mRNA strand coincides with the spatial arrangement of these polysomes<sup>6</sup>. Gradient analyses of polysomes obtained by most investigators, however, show an equal distribution of various classes of polysomes. Since, due to the manipulations involved in the preparation of gradients, the contamination by RNases cannot be excluded, the degradation of pentamers to smaller units would be expected. The extreme sensitivity of polysomes to RNases was established by several groups. Mathias *et al.*<sup>24</sup> have demonstrated that even after sucrose gradient fractionation, all sizes of polysomes were found in electron micrographs taken from the fast sedimenting fractions. The omnipresence of RNases is a major disadvantage in all nucleic acid work. (Recently, E. Glowacki has shown that two major brands of creatine phosphokinase contain RNase activity, which is not destroyed by heating at 80° C (personal communication).) By disrupting the cells the balanced equilibrium inside the cell is disturbed and the probability of RNase action increases greatly. The occurrence of labelled monosomes with the continuation of the synthesis in cell-free systems, which is absent during whole-cell incubation, could be explained by RNase action on the mRNA strand. This process might be facilitated by the exposure of mRNA during the movement of the ribosomes. If, however, the detachment of monosomes with the completion of the growing peptide chain does not occur in whole cells, it is reasonable to assume that the limiting factor or factors for the protein synthesis have to intervene either before the arrangement of the amino-acids on the ribosomes or after the polypeptide chain is released from the polysomes. Our results clearly demonstrate that in whole cells the decrease of protein synthesis is independent of the polysome structure; they do not offer an explanation for the mechanism involved in the declining haemoglobin

synthesis in reticulocytes. Further experiments are necessary to investigate this point.

According to present-day concepts the breakdown of polysomes and the reattachment of monosomes to the ribosomal cluster are pre-requisites of protein synthesis<sup>2,7,9,11</sup>. Experiments with whole cells could not demonstrate the appearance of labelled monosomes in the cell at any time. Unless the release of the polypeptide chain in whole cells is much faster than in cell-free systems, the mechanism is different under the two experimental conditions. Differences with respect to the system were found in the replication of DNA: *in vivo* only one strand of the template is copied<sup>25</sup>, while in a purified system RNA is transcribed on both strands of the DNA duplex<sup>26</sup>. The reattachment of ribosomes to the polysome cluster *in vitro* was demonstrated by two groups<sup>7,8</sup>, however, in both cases, the monosomes attached preferably to the lighter polysomes instead of the expected equal distribution throughout the polysome peak.

In view of these observations, an alternative hypothesis for polysome function will be presented here. If the polysomes are arranged in closed circle configuration, as they actually appear in electron micrographs<sup>8,25</sup>, ribosomes, carrying the growing peptide chain, could move along the circular mRNA without being released. The information for the release of the completed chain and for the beginning of a new one would be imprinted somewhere on the mRNA molecule. The polysomes in this model would probably act more efficiently than if they were arranged along an extended mRNA strand with single ribosomes moving from one end to the other, detaching there and attaching on the other end of the strand again. The observation that the limitation of the synthesis is independent of the breakdown of polysomes in whole cells favours such a model.

## A BIOACTIVE SUBSTANCE IN THE CAECUM OF GERM-FREE ANIMALS

## Demonstration of a Bioactive Substance in Caecal Contents of Germ-free Animals

IT was recently reported<sup>1</sup> that the supernatant of caecal contents from germ-free animals contains a substance (or substances) which is (a) toxic on parenteral administration and which (b) affects smooth muscle organs *in vitro* and cardiovascular function *in vivo*. Caecal contents from comparable conventional control animals showed such activities only in substantially reduced form.

**Preparations.** Germ-free mice (Swiss Webster) and rats (Wistar), reared under standard conditions<sup>2,3</sup>, fed uniformly steam-sterilized diet (L-462) (ref. 4) and killed by a blow on the head were used as donors. Caecal contents were diluted with saline to 15 per cent dry matter and centrifuged at 97,000*g* for 30 min. The caecal supernatant (CS) of germ-free (gf) and conventional (conv) animals obtained in this manner was essentially isosmotic with blood; pH was maintained at 6.8.

**Toxic effects.** Toxicity of mouse CS was tested by injecting it intraperitoneally into young, 20 g conventional mice. The results of these observations, shown in Fig. 1, indicate for CSgf an  $LD_{50}$  of approx. 0.5 ml.; CSconv in comparable doses was relatively non-toxic. The germ-free preparation, when lethal, killed the mice within 30 min to 6 h. The main symptoms were: skeletal muscle paralysis, cardiovascular distress and, terminally, respiratory failure. On autopsy, intensive vasodilatation was apparent in the abdominal viscera. In laparotomized

germ-free mice under pentobarbital sodium anaesthesia (35 mg/kg body-weight), extrusion of small amounts (about 0.5 ml.) of their own caecal contents into the peritoneal cavity was lethal in less than 1 h after successive wound repair. It is calculated that a germ-free mouse contains in its caecum 5- to 8-fold of its own lethal dose. Preliminary observations carried out with rat CS indicate the same trend. Toxicity of mouse and rat CSgf appears to be fairly similar, qualitatively and quantitatively.

**Effects on smooth muscle and on the cardiovascular system.** CS preparations cause contraction of the isolated rat uterus and guinea-pig ileum *in vitro*. A summary of these observations, in comparison with the effects of other musculo-active substances, is given in Table 1a. As the actions of CSgf aligned best with those of bradykinin, this peptide (synthetic bradykinin, Sandoz) was used as standard in a 'four-point assay' test<sup>5</sup>. A representative sample of mouse CSgf indicated an activity per ml. which was equivalent to  $0.64 \pm 0.13 \mu\text{g}$  bradykinin ( $\pm$  is S.E.). The slope of regression lines for bradykinin and CS was not significantly different ( $P < 0.05$ ). In this work Krebs-Henseleit solution was used with a 10 per cent aliquot of the calcium chloride added. The rat uterus was in oestrus; temperature was 37°C; the data refer to a 15-ml. muscle bath.

Table 1. ACTIONS OF GERM-FREE MOUSE (RAT) CAECAL SUPERNATANT

	CSgf	BK	ACH	5HT	HIST
(a) Isolated uterus (rat)					
No pre-treatment	+	+	+	+	0
Atropine sulphate 0.1 mg, D-lysergic acid diethylamide tartrate 1 mg/ml. bath	+	+	0	0	
Isolated ileum (guinea-pig)					
Atropine sulphate 0.1 mg, D-lysergic acid diethylamide tartrate 1 mg, triptenamine hydrochloride 1 mg/ml. bath	+	+	0		0
(b) Blood pressure (rat)					
No pre-treatment	↓	↓	↓		↓
Atropine sulphate 5 mg, triptenamine hydrochloride 6 mg/kg body-wt.	↓	↓	0		0
Blood pressure (dog)					
No pre-treatment	↓	↓	↓		↓
Cardiac output (rat)	↑	↑	↑		↑
Blood flow, intestines, liver (rat)	↑	↑			

CSgf, germ-free caecal supernatant; BK, synthetic bradykinin (Sandoz); ACH, acetylcholine chloride; 5HT, 5-hydroxytryptamine; HIST, histamine diphosphate.

+, contraction or positive effect; ↑, increase; ↓, decrease; 0, no effect.

Fig. 1. Mortality of mice receiving intraperitoneal injection of caecal supernatant. Donors, gf and conv mice, young adults, ♂ ♀, L-462 steril. diet; recipients, conv mice, 6 weeks old, ♂, approx. 20 g body-wt., practical ration; +, germ-free caecal supernatant, 16 recipient mice per group; O, conventional caecal supernatant, 12 recipient mice per group. No. of deaths in brackets

CSgf containing activity which is comparable to the hypotensive doses of bradykinin causes pronounced fall of blood pressure in rats and dogs and an increase in cardiac output and regional blood flow in rats (mainly in the intestines and in the liver) on intravenous administration. These effects are temporary, lasting a few minutes. A summary of these observations along with results obtained with other hypotensive drugs are given in Table 1b. A parallelism between the actions of CSgf and bradykinin was also indicated in these instances. Blood pressure was recorded with a mercury manometer in the cannulated carotid (rat), or femoral artery (dog) under pentobarbital sodium anaesthesia (35 mg/kg body-weight). Cardiac output and regional blood flow were determined in rats (same anaesthesia) by the method of Sapirstein<sup>6</sup>. The time lapse between the intravenous injections of the drug or CSgf and of the indicator used (about 1  $\mu\text{C}$ . of  $^{86}\text{RbCl}$ ) was 75 sec.

**Occurrence of active substance in reference to species, diet and GI segment origin.** So far the occurrence of the active substance was ascertained only by its effects on smooth muscle. The substance was found present in caecal contents of young adult germ-free mice in comparable quantities, irrespective of the diet used. The diets were: steam-sterilized L-462, Purina 5010 C (closed

formula diet of Ralston Purina, Inc., St. Louis, Missouri), or the liquid diet of Greenstein *et al.*<sup>7</sup> sterilized by filtration (supplied by courtesy of General Biologicals, Chagrin Falls, Ohio). Germ-free mice and rats contain the substance in 6- to 8-fold concentration in comparison to their conventional controls. Among animals fed the same diet (steril. L-462), rats showed substantially higher levels of active substance than mice, irrespective of their microbiological status. Increased amounts of the substance in the GI tract of germ-free mice over conventional controls were clearly demonstrable in the ileum. However, the greatest discrepancy in this respect was attained in the caecum. In the colon and in the voided faeces the difference was waning.

**Physico-chemical and chemical properties of substance.** As yet these properties have been investigated only in reference to the effects of CS on smooth muscle.

(a) **Storage.** When stored at  $-18^{\circ}\text{C}$  for a period of 6 months, rat and mouse CSgf were found to retain at least 60 per cent of their original activity. Freezing and thawing (up to 10 times) were well resisted.

(b) **pH and temperature.** The substance (tested in mouse CSgf) appeared to be stable between pH 1 and 8 at room temperature over a period of at least 1 h. At temperatures higher than  $70^{\circ}\text{C}$  (pH 6-8, exposure 10 min and over) the activity was rapidly lost.

(c) **Dialysis.** On initial qualitative tests, the substance (from mouse CSgf) was found to pass a cellulose dialysis membrane (Fischer Scientific Co., Pittsburgh, Pennsylvania). In succession, quantitatively run observations indicated that during a period of 24 h at  $1^{\circ}\text{C}$  only a very small fraction of the substance was capable of passing the membrane.

(d) **Precipitation.** The active substance (tested in mouse CSgf) could be 'salted out' by saturation with ammonium sulphate. On successive dilution with saline, the precipitate was redissolved and a considerable proportion of the activity recovered.

(e) **Digestion.** Chymotrypsin, in conditions which were found to degrade bradykinin, did not alter appreciably the activity of mouse CSgf.

(f) **Adsorption.** It was found that various cationic exchange resins ('Dowex 50 X-4', 'Rexyn RG 51 H', 'Amberlite CG 50', 'Biorex 70') absorb the active substance and that, on successive elution with weak alkali, considerable proportions of the activity can be recovered. This method is at present used in column chromatography for initial purification of the active principle.

**Comments.** The toxic and musculoactive principles in caecal contents possibly represent two groups of substances. This is suggested by the observation that mouse and rat CSgf proved equipotent in terms of toxicity, while they are greatly different in terms of concentration of the musculoactive substance.

The close similarity in pharmacological effects between the musculoactive substance and bradykinin, the resistance of these effects to acetylcholine-, histamine- and serotonin-blocking drugs, as well as common adsorbability to cationic exchange of resins, indicate that the musculoactive substance belongs to the group of hypotensive peptides. Dependence on temperature and pH, the characteristics shown in the dialysis, precipitation and digestion experiments, suggests that we deal with a compound of higher molecular weight than bradykinin. In this context it should be noted that in the concentration of pancreatic and salivary kallikrein<sup>8</sup> and in that of caecal musculoactive substance the same species dependence seems to exist. In both instances the values observed in rats are 10-15 times higher than those in mice.

In normal life the intestinal flora appears to be directly or indirectly engaged in the inactivation of the toxic and musculoactive agents. In germ-free animals, that is, in absence of the flora, these substances accumulate in the gut lumen and may participate in the development of the anomalies which are observed in the lower bowel of

these animals (greatly distended and enlarged caecum, more liquid contents of the lower bowel).

### Reduced Levels of a Bioactive Substance in the Caecal Content of Gnotobiotic Rats Mono-associated with *Salmonella typhimurium*

THE presence of elevated levels of a bioactive substance in the caecal content of germ-free rodents<sup>1</sup> has led us to speculate that this material may contribute to the enlargement of the caeca in these animals. The enlarged caecum, with its more liquid contents, is the most pronounced anomaly in the germ-free rodent. The reduction in the volume of the caecal contents and weight of the caecum is brought about by the introduction of the 'normal flora'<sup>2</sup> and occasionally by a single bacterial species<sup>3</sup>. The investigation recorded here was designed to determine whether the presence of *Salmonella typhimurium* (Lobund strain 750A), which was previously shown by the Lobund group to cause transient caecal reduction in the germ-free rat<sup>4</sup>, was also involved in the release or inactivation of the bioactive substance.

Six male and six female young adult germ-free rats (Wistar strain) were infected *per os* with a saline suspension of *Salmonella typhimurium* 750A. The animals were maintained in flexible plastic isolators<sup>5</sup> and fed autoclaved diet (L-462)<sup>6</sup>. At 2, 6, 17 and 45 days, groups of three rats were removed from the isolator, weighed, decapitated and the blood collected for immunological examination. Comparable untreated germ-free and conventional rats served as controls. After the caeca were removed and weighed, their contents were collected and the empty caeca reweighed. In the pooled caecal contents of various groups, bacterial counts were taken. In succession, the contents were treated and assayed for the musculoactive substance as described in the preceding communication.

Table 1 shows that in the untreated germ-free rats removed prior to infection (zero day) the caeca were enlarged and the level of the musculoactive substance was elevated. After 2 days of exposure to *S. typhimurium* the reduction of the size of the caecum was evident and the amount of bioactive substance had dropped below the quantity usually found in conventional caecal content. At this time the number of *S. typhimurium* averaged  $1 \times 10^9/\text{g}$  wet content. On the 6th and 17th days, the size of the caecum was still decreasing, but the amount of active substance showed some increase at these sampling periods. After 45 days of exposure, the size of the caecum

Table 1. CERTAIN CHARACTERISTICS OF CAECAL CONTENTS IN GNOTOBIOTIC AND CONVENTIONAL RATS

	Germ-free	Ex-germ-free ( <i>S. typhimurium</i> , oral inoc.) Days of exposure				Conventional
		2	6	17	45	
Weight of caecal contents g/100 g body-weight	11.8	4.4	3.5	1.8	7.1	0.7
Musculoactive substance in caecal supernatant, $\mu\text{g}$ BK equiv./ml.	18.6	0.6	1.3	2.8	10.3	2.5

Count of *S. typhimurium* was about  $1 \times 10^9/\text{g}$  wet caecal contents in all monocontaminated rats. 3-10 rats per group.

and the uteroactive substance had returned to about two-thirds of that found in the germ-free animal, yet the numbers of *S. typhimurium* in the caeca remained elevated. Circulating antibodies were not detected on the 6th day, but an agglutinin titre of 1:512 was obtained with serum from the rats killed on the 45th day.

When another group of 6 germ-free rats was contaminated orally with caecal content from the 45-day mono-associated rats, caecal reduction was evident within 48 h. One of the germ-free rats receiving the *Salmonella*-containing caecal content died 1 day after exposure. This suggests that the virulence and caecal-reducing potential of the bacterium was not altered during its 45-day association with the gnotobiotic rats.

The results of this work were similar to those obtained in a previous experiment in which *S. typhimurium* was superimposed *per os* in gnotobiotic rats monoassociated with an innocuous intestinal bacteroid species<sup>7</sup>.

The apparent parallelism which exists between the fall and rise of the musculoactive substance in caecal contents and the transient nature of the caecal reduction on monocontamination permit the speculation that there was causal relationship between these two phenomena. The appearance of circulating antibodies suggests that

the host overcomes the infection by responding immunologically to the infection. This response, while protecting the host, places the animal in a carrier state—a state which allows the persistence of high numbers of *S. typhimurium* in the intestinal tract, but permits the animal to re-assume the characteristics of germ-freeness.

## MITOTIC HOMEOSTASIS

By PROF. W. S. BULLOUGH

Birkbeck College, University of London

AND

DR. T. RYTÖMAA

Department of Pathology, University of Helsinki

IT has long been obvious that each of the tissues of an adult mammal has its own characteristic average mitotic rate which is in balance with its average rate of cell death. From time to time the point of balance may alter, but the balance itself remains. It is also well known that after a period of cell damage or destruction most tissues are able to react by developing an abnormally high mitotic rate which persists during the period of repair and, further, that certain tissues possess a capacity for increasing their mitotic rate as a response to some special physiological demand. A knowledge of the homeostatic mechanisms that underlie these various mitotic phenomena is obviously of fundamental biological importance, and it is equally obvious that no real understanding of the problem of cancer, which must involve a partial or complete breakdown of these mechanisms, is likely to be achieved until this knowledge is obtained.

The problem of mitotic control has often been discussed<sup>1</sup> and it has commonly been suggested that humoral substances may be involved acting as inhibitors in a negative feedback mechanism, as stimulants in a positive feedback mechanism, or as both. It is sometimes implied that such substances may have a generalized action within the body<sup>2</sup>, but the mitotic independence of the various tissues indicates clearly that each must possess its own specific mitotic control mechanism.

In the past few years considerable new information has been obtained, especially regarding mitotic control by negative feedback in epidermis<sup>3</sup> and by both negative and positive feedback in the granulocytic and erythrocytic systems<sup>4,5</sup>. Although this and other information now available relates only to a few tissues or organs, it is becoming increasingly obvious that all mitotic control mechanisms have certain common themes and that the various situations found in different tissues are merely variations on these themes. This article represents a new assessment of the evidence and it indicates some of the essential features of mitotic homeostasis in the whole body.

It is a pleasure to record that the exchange of views which led to the present statement was made possible by travel grants from the University of Helsinki and from the

Damon Runyon Memorial Fund for Cancer Research, New York.

### Mitotic Control by Chalones

In recent years much information has been obtained to indicate that certain tissues contain, and presumably produce, substances which depress mitotic activity<sup>3</sup>. Such substances have been termed 'chalones', and each appears to be tissue-specific in that it acts only on its tissue of origin. The first chalones to be extracted were those of the liver and kidney, and they were found to be water-soluble, non-dialysable and relatively unstable<sup>6</sup>.

More recently an epidermal chalone has been extracted and has been found to depress mitosis in normal epidermis and in the corneal and oesophageal epithelia<sup>3</sup>. It has similar physical characteristics to the liver and kidney chalones. In normal epidermis the mitotic rate appears to be inversely proportional to the chalone concentration within the cells, and this, together with the inherent life expectancy of the cells, evidently determines the size of the cell population. When epidermal cells are damaged there appears to be a decrease in the rate of chalone production, an increase in the rate of chalone loss, or both, and the consequence is a local increase in the mitotic rate. The mitotic rate returns to normal only after a sufficient number of new and normal cells have been produced to establish once again the normal chalone concentration in the affected area.

Still more recently a granulocytic chalone has been extracted from serum containing mature granulocytes, and its characteristics also resemble those of the other chalones<sup>4</sup>. The mitotic activity that leads to the production of granulocytes occurs in precursor cells in the bone marrow as part of the process of granulopoiesis. The mature granulocytes are finally released through the blood to the tissues, where their ultimate fate is death<sup>7</sup>. It is these mature cells which evidently contain the chalone that inhibits mitosis in the precursor cells.

There is also strong evidence for the existence of an erythrocytic chalone. It is known that erythrocyte production may be suppressed after an adequate erythrocyte transfusion, and it has recently been found that the serum

from rats containing extra transfused erythrocytes depresses the rate of erythrocyte production in bone marrow *in vitro*<sup>4</sup>.

It is important to note that, at least in the epidermis, the chalone itself does not appear to be fully functional and that the effective mitotic inhibitor may be an unstable chalone-adrenalin complex<sup>3</sup>. This observation provides an explanation for the well-known diurnal mitotic rhythm in the epidermis: in sleeping mice, with low output of adrenalin, the complex breaks down and the mitotic rate rises; when the mice wake up the output of adrenalin rises, the complex re-forms and the mitotic rate falls. It is important to note that a recent survey has shown that a diurnal mitotic rhythm essentially similar to that in the epidermis has been described in at least 15 other tissues<sup>8</sup>, and the obvious inference is that in all of them mitotic control may be exercised through unstable chalone-adrenalin complexes. The tissues which do not show any obvious diurnal mitotic rhythm are those in which the mitotic rate is either very low or very high, or in which it is hormone-dependent.

Other evidence indicating the existence of basically similar mitotic control mechanisms in a variety of tissues comes from mitotic reactions to wound healing and regeneration. In epidermis the infliction of a wound evidently results in a reduced chalone concentration in the closely adjacent cells and a consequent local increase in the mitotic rate, which because of the lack of chalone shows little if any diurnal rhythm<sup>3</sup>. This local mitotic reaction has the form of a gradient with a length of about 1 mm and with the highest point at the wound edge. Similar local mitotic reactions have been described in all tissues which have been studied from this point of view<sup>8</sup>, and it is also important to note that the reaction to wounding is tissue-specific<sup>9</sup>.

As regards the general mitotic reaction seen during regeneration, the large literature is confusing and contradictory and much of the published work is of doubtful significance. A critical survey has recently been prepared<sup>8</sup>. However, in the case of the liver it has been clearly shown that, when the damaged tissue exceeds about 10 per cent of the whole, the local wound reaction begins to be accompanied by a general reaction whereby the mitotic rate rises throughout the whole liver<sup>10</sup>. Beyond this point the intensity of the general mitotic response is in direct proportion to the percentage of tissue destroyed. Such a quantitative relationship is, of course, exactly what would be expected when a local chalone shortage due to wounding gives place to an increasing general chalone shortage due to the decreasing amount of normal tissue within the total body space. It has indeed been shown that a damaged kidney loses all its detectable chalone<sup>6</sup>.

**Site of chalone action.** In considering the possible points of chalone action within the affected cells, it is necessary to consider the cycle of phases through which a cell passes from one mitosis to another<sup>11</sup>. These are: *dichophase*, when the cell 'decides' whether to prepare for another mitosis or whether instead to prepare for function within the tissue; *prophase*, the period of preparation for mitosis which includes the phase of DNA synthesis (or *S*) and the antephase (or *G<sub>2</sub>*); *mitosis* itself; and *apophase*<sup>8</sup>, when each daughter cell re-establishes its normal synthetic mechanisms and grows to full size.

Since the effect of the presence of a chalone is to reduce the number of cells preparing for mitosis, it is evident that its main action must be exerted prior to the prophase, probably in the dichophase. Indeed, the implication is that the 'decision' taken by a cell in the dichophase may be dictated by the intracellular concentration of the chalone, which determines the type of synthetic activity in which the cell will indulge. Thus, in the absence of sufficient chalone the cell will embark on that series of enzyme syntheses that characterizes the prophase, while in the presence of sufficient chalone it will synthesize

those enzymes needed for typical tissue function. Any such 'decision' relating to synthetic activities is most likely to involve gene action, and indeed the situation is strongly reminiscent of that in micro-organisms in which the activity or inactivity of particular regions of the genome is determined by substances called 'effectors'<sup>12</sup>. A micro-organism is capable of many alternative syntheses that can be activated or inactivated in this way, but any typical cell in an adult mammal may be capable of only two. These may be under the control of two groups of genes, which for simplicity may be termed respectively the 'mitosis operon' and the 'tissue operon'.

Chalones are evidently tissue-specific substances, and if they act at gene level this can only mean that the operon on which they act must also be tissue-specific. Although it is not yet certain whether the 'mitosis operon' can be regarded as tissue-specific, it is obvious that the 'tissue operon' must be. The possibility, therefore, arises that chalone action may be to promote the functional activity of the tissue cells and that the inhibition of mitosis may be the secondary outcome of this action.

This could explain why so many cells when released from normal chalone control, whether by incubation *in vitro*, or during local or general regeneration, or in neoplasia, merely revert to the basic function of all cells, which is to grow and to divide indefinitely. It would also indicate that the state of functional maturity of most adult tissues must be regarded as unstable in that throughout life it needs always to be supported by adequate concentrations of the appropriate chalones.

**Length of mitotic cycle.** The operon theory of chalone action could also provide an explanation for the length of time a cell remains in dichophase: with a low chalone concentration the cell should immediately pass into prophase, with a high concentration it should immediately begin synthesis for tissue function, but with an intermediate concentration it might remain poised between these two alternatives for an indefinite time. It should follow that with a decreasing chalone concentration, not only should more cells tend to enter mitosis but also they should tend to pass through the mitotic cycle more quickly, and indeed it is well known that in wounds or during regeneration this does occur. It is also well known that these shorter cell cycles are due mainly to a reduction in what has been commonly called the *G<sub>1</sub>* period. In the present terminology this comprises the apophase, dichophase, and the pre-DNA synthesis period of the prophase, and of these it is only the dichophase which is likely to be capable of any great variation in length.

However, although the main action of a chalone on the duration of the mitotic cycle may be exerted in the dichophase, it is now clear that in both the epidermis and the granulocytic system the chalone concentration also affects the speed of the whole process prophase-mitosis, although in both tissues there is a maximum speed that cannot be exceeded. In the granulocytic precursor cells of a normal animal, preparation for mitosis is already proceeding at this maximum speed, but, if through an excess of chalone the mitotic rate is reduced, so also is the speed at which the cells enter and pass through DNA synthesis<sup>4</sup>. In normal epidermis, where the mitotic rate is lower, the speed at which cells pass through antephase-mitosis is moderate: with increasing chalone concentrations fewer cells proceed at a slower rate, while with decreasing chalone concentrations more cells proceed at a faster rate until the maximum speed is reached<sup>13</sup>.

It appears that the most sensitive periods are the dichophase and the antephase, both of which may be blocked by excess chalone, while the least sensitive periods are the phases of DNA synthesis and of mitosis, both of which may be slowed but apparently not stopped. This might be taken as evidence that a chalone does exercise some direct inhibitory action on mitosis, in which case it might follow that the mechanism of mitosis may contain one or more tissue-specific components.

*Types of tissue cells.* It has been suggested that, in any typical tissue, specialization for mitosis and specialization for function are merely opposite expressions of the same homeostatic mechanism. At any given moment a tissue rests at a point of balance with a certain proportion of its cells involved in mitosis, a certain proportion involved in functional activity, and the remainder poised part-way between the two. The position of this point of balance varies widely in different tissues so that, for example, within the crypts of Lieberkühn a relatively large percentage of the cells are involved in the mitotic cycle, while in epidermis the percentage is much smaller.

Further consideration of such examples indicates that a typical tissue is composed of at least four distinct types of cells (see Fig. 1): the progenitor cells (*P*), which are involved in the mitotic cycle; the immature cells (*I*), which are preparing for tissue function; the mature cells (*M*), which are specialized for tissue function but which if the effective chalone concentration falls are capable of reversion to mitosis; and the mature cells (*D*), which are also specialized for tissue function but which are moving towards death and are unable to revert to mitosis.

In epidermis, *D* includes only the few cells of the stratum granulosum, whereas in the granulocytic system it includes the large group of mature granulocytes distributed between bone marrow, blood and tissues, and in the erythrocytic system it includes the large group of the non-nucleated erythrocytes. Cells leave *D* only to die.

It must be stressed that the borders between the four groups of cells are not necessarily sharply defined; rather, they should be regarded as broad zones across which one cell type grades into the next. It must also be stressed that the functional cells may be those of type *M* as in the liver, or those of type *D* as in the granulocytes and erythrocytes, or possibly in some tissues those of both type *M* and type *D*.

Fig. 1

The mitotic rate of the tissue illustrated in Fig. 1 is expressed partly by the size of *P* and partly by the fact that, within limits, the larger the size of *P* the faster the speed at which the cells prepare for mitosis. The rate of production of new cells determines the rate of flow of the cells from left to right, and at the point of balance the cell production rate exactly equals the cell death rate. The size of *P* is inversely proportional to the concentration of the chalone complex in the tissue, and it appears probable that the chalone may be produced mainly by the cells in *M* and *D*. Thus the chalone concentration is a function of the size of *M* and *D*, of the rate of synthesis, of the stability of the molecule, and of the rate of loss both from the tissue and from the body.

*Life expectancy of the mature cells.* In normal circumstances the chalone concentration appears to be relatively constant, but if its efficiency is increased by the addition of extra adrenalin, then mitosis is further inhibited, which means that *P* is reduced in size and that its cells also prepare for mitosis more slowly. It has been observed in epidermis and sebaceous glands that when, in stress, the mitotic rate is reduced to about a quarter of the normal, the mass of the tissue ( $P+I+M+D$ ) remains unchanged for at least a month<sup>14</sup>, which must indicate that the rate of flow through the system and the rate of cell death are both equally reduced. This new situation is expressed in Fig. 2, in which it is suggested that the chalone-adrenalin complex has pushed the *M*-*D* barrier to the right, although, of course, the rate of cell death

would equally be reduced if the chalone complex acted directly on the *D*-death barrier. In either case the reduced rate of flow from mitosis to death must mean an increase in the average life-span of the mature cells.

The opposite situation of relative chalone inefficiency follows the withdrawal of adrenalin, for example, after adrenalectomy. In these circumstances in epidermis the mitotic rate increases about three times<sup>3</sup>, but again there is no evidence of any alteration in the tissue mass. Thus the increased rate of cell production must have been offset by a shorter life-span of the functional cells. A more extreme situation can be obtained through chalone shortage induced by any form of cell damage. The resulting high mitotic activity is again accompanied by a reduced life-span of the mature cells, as has been shown both in the cirrhotic liver<sup>15</sup> and in psoriasis<sup>16</sup>. In the latter, the life of the maturing epidermal cells is reduced from a normal average of 27 days to a new average of about 4 days.

Fig. 2

It thus appears that if the primary action of a chalone is to promote those specific syntheses that are essential for tissue function, then this action has two consequences: the suppression of mitosis and the promotion of cell survival. It could be argued that longer cell survival might be the consequence of the increased efficiency of the tissue-specific syntheses, especially in *M*.

It is also important to note that the inverse relationship between the rate of cell production and the life expectancy of the mature cells only operates within limits to maintain the normal tissue mass, and that beyond these limits the tissue mass may change. Thus the high epidermal mitotic rate which results from continued irritation is accompanied by a moderate increase in epidermal thickness, and the tissue becomes stabilized at a new point of balance.

*Conclusions.* The main conclusion arising from this survey is that in most tissues mitotic homeostasis may be ensured by the effector-like action of a chalone, the concentration of which determines whether the 'mitosis operon' or the 'tissue operon' is active. However, in such tissues as nerves and striped muscle, which never show any mitotic activity, there is evidence that the 'mitosis operon' may be permanently blocked and that the synthesis of tissue proteins may be dictated at the ribosome level rather than at the DNA level. In such circumstances a chalone mechanism would be redundant.

Not only does a chalone inhibit mitotic activity but it commonly also lengthens the life expectancy of the mature cells. The consequence is that moderate changes in the mitotic rate leave the tissue mass unchanged, although large changes in the mitotic rate may result in moderate changes in the tissue mass. It also appears that the life expectancy of the mature cells is in some degree tissue-specific, and it may be suggested that the size of any tissue within the total body space and the mitotic activity of that tissue may be a function of the rate of chalone production and of the life expectancy of the mature cells. Thus, for example, a tissue of large mass and low mitotic rate may be characterized by a low rate of chalone production and a long cell life.

Adrenalin, and possibly also a glucocorticoid hormone, commonly acts to strengthen chalone function, and since the homeostatic mechanism was obviously evolved in wild animals it may only operate efficiently in conditions of moderate stress. Unstressed laboratory animals, like

tissues and organs *in vitro*, may present an abnormal situation with weakened mitotic control. The role of the adrenal glands in a stressful situation, such as starvation, is to reduce the mitotic rate and to prolong the functional cell life, and the survival value is obvious.

### Other Specific Control Mechanisms

Although it is possible that, in mammals, local or general tissue regeneration may be explicable mainly or even entirely in terms of chalone action, it is obvious that in certain tissues the mechanisms of mitotic homeostasis must be more complex. In particular, it is well known that in some tissues mitotic activity is hormone-dependent while in others the rate of cell renewal is at least partly poietin-dependent. These are tissues which, from time to time, must be able to increase the rate of cell production and also the tissue mass in response to physiological demand.

**Mitogenic hormones.** In tissues in which growth is dependent on mitogenic hormones the reaction to the presence of the hormone is two-fold: the mitotic rate increases, and the new cells so produced become functionally active. Thus, when the vaginal epithelium is stimulated to mitosis by oestrogen it also actively produces keratin, and when the thyroid is stimulated to mitosis by thyrotropin it also actively produces and secretes the thyroid hormone. An analysis of the details of this type of reaction in the vaginal lining indicates that in the absence of the mitogenic hormone the tissue rests at a point of balance characterized by a small mass, a negligible mitotic rate, and a long cell-life expectancy. All the cells appear to be of type *M* and to be non-functional. The effect of the addition of oestrogen on the point of balance in the tissue is illustrated in Fig. 3. First, many of the cells revert to type *P* and indulge in high mitotic activity, and then, as new cells are formed, these pass back through *I* to *M*. However, the new mature cells have a much shorter life expectancy, which has been estimated to be between 30 and 45 h<sup>17</sup>, and they, therefore, pass beyond *M* into *D*. It is this final type of cell which is functional and which actively produces keratin before it dies.

Fig. 3

Although in this type of tissue the greatly increased mitotic rate is partially offset by the reduced life expectancy of the mature cells, it nevertheless results in a moderate increase in tissue mass. The tissue then comes to rest at a new point of balance, and it remains there as long as the hormone stimulus is maintained.

Although it is only possible to speculate, the simplest hypothesis is that a mitogenic hormone, either directly or

indirectly, specifically neutralizes the chalones of its target tissues, the reaction then being basically due to chalone shortage. In support of this, a detailed analysis has indicated many close similarities between a hormone reaction and a wound reaction<sup>8</sup>, but even more important has been the recent suggestion that in mammary gland *in vitro* mitotic activity may develop when a sub-threshold hormone stimulus is added to a sub-threshold wound stimulus<sup>18</sup>.

Thus a mitogenic hormone may be regarded, at least tentatively, as part of a control mechanism which is imposed on the basic chalone mechanism. In response to some trigger stimulus, usually originating outside the animal, the hormone is produced and the hormone-dependent tissue is enabled to increase both in size and in functional activity. A typical example is the well-known effect on the ferret of an increase in day-length in spring which activates the pituitary gland to stimulate the gonadal production of oestrogens or androgens.

**Poietins.** There are at least three important tissues, the erythrocytic, granulocytic and lymphocytic systems, which appear to possess unusually complex mechanisms for the control of cell production. Unlike the hormone-dependent tissues their basic condition would seem to be one of relatively high mitotic activity which, at least in the erythrocytic and granulocytic systems, is controlled by a normal chalone mechanism<sup>4</sup>. The mature erythrocytes and granulocytes differ from such ordinary tissues as epidermis in that their life expectancy seems to be unrelated to the mitotic rate of the progenitor cells. The average life of a rat erythrocyte is about 60 days; the life of a granulocyte is unpredictable since the death of these cells is usually determined not by age but at random. Granulocytes die shortly after they have functioned as scavengers<sup>7,19</sup>.

The process of erythrocyte production, called erythropoiesis, is dependent partly on the mitotic activity of the erythrocytic precursor cells and partly on the production of new progenitor cells by the transformation of stem cells, which also evidently possess the alternative potentiality of transformation into granulocytes<sup>20,21</sup>.

In the erythrocytic system the chalone, which may perhaps be produced in the circulating erythrocytes, seems to influence only the mitotic activity of the progenitor cells in the bone marrow<sup>4</sup>, and in the usual way it may help to maintain the tissue mass. However, this is a tissue which must be able to adjust its rate of cell production not only in terms of mass but also in terms of function. Thus a reduced oxygen tension increases the functional demand for oxygen and results in the rapid production of erythrocytes in excess of the normal number. It is now known that this reaction depends on the active secretion of the substance erythropoietin<sup>5</sup>, although the secretion site is not yet known.

The mode of action of erythropoietin in stimulating the rate of cell production is quite unlike that of a mitogenic hormone. A survey of the large literature indicates that it does not change significantly either the mitotic rate of the erythrocytic progenitor cells, or the maturation rate of the developing erythrocytes<sup>22</sup>. Its primary action is to promote the conversion of stem cells into erythrocytic progenitor cells<sup>20,22</sup>.

An important question thus arises as to the nature of these stem cells, of which unknown numbers are present in bone marrow. Since it is generally agreed<sup>19-21</sup> that they may give rise to the cells of at least two distinct tissues, the erythrocytic and granulocytic systems, it is evident that they must be regarded as pluripotential cells in which final differentiation has not yet occurred. Thus the conversion of stem cells into erythrocytic progenitor cells must be regarded as an essentially embryonic process of differentiation, and erythropoietin must be regarded as an inducing substance. Little or nothing is known of the way in which the stem cell population maintains its numbers<sup>20</sup>, but it is obvious that as its cells are lost by

differentiation the remaining stem cells must recruit their numbers by mitosis. The implication is that a mitotic homeostatic mechanism must exist and it is possible that this may be controlled by a chalone mechanism. A further implication is that the cells which are recognizable as belonging to the erythrocytic tissue may not be self-maintaining. The mitotic activity of the progenitor cells appears to result more in the production of large numbers of erythrocytes than in the production of more progenitor cells.

The situation in the granulocytic tissue seems to be essentially similar to that in the erythrocytic tissue in that the cells are recruited from the stem cell population by the action of an inducing substance, called granulopoietin, and in that the progenitor cells undergo a series of mitoses which are controlled by a chalone. The probable relation of the erythrocytic and granulocytic systems to the stem cell population is illustrated in Fig. 4.

Fig. 4. Diagram of the relations of the erythrocytic (Ery) and granulocytic (Gran) systems with the stem cell population (S). Differentiation is induced either by erythropoietin (Ep) or granulopoietin (Gp).

A substance that has been called 'granulopoietin' has been obtained from rat serum and has been partly purified<sup>4</sup>, and it has been shown to increase the number of functional granulocytes produced. However, analysis has indicated that this increase may be due more to the increased mitotic activity of the progenitor cells than to the differentiation of the stem cells<sup>4</sup>. Thus the status of this substance is not yet clear, and it may be wiser to reserve the name granulopoietin for whatever factor is finally shown to induce the formation of the granulocyte progenitor cells.

**Antigens.** The only other major tissue of the adult mammal which has been clearly shown to be dependent on a stem cell population is the lymphocytic system. This appears to be in some way related to the erythrocytic and granulocytic systems, and it has even been suggested that all three may be derived from the same stem cells<sup>23</sup>. Although less is known about the manner of cell gain and cell loss in the lymphocytic system, there is sufficient evidence to indicate a basic similarity with the erythrocytic and granulocytic systems.

There is still considerable argument concerning the identity and the activity of the lymphocytic stem cells<sup>23</sup>, but it is possible that they may produce their own 'mature' type of cell, which may be the small lymphocyte. If this is true, then the normal high rate of small lymphocyte production must indicate an equally high rate of loss, either through differentiation or death, and the continuing balance of the stem cell population must indicate the existence of a mitotic homeostatic mechanism. In this connexion it is interesting to note that granulocytes can depress mitotic activity in lymphocytic stem cells<sup>24</sup>, and this may perhaps mean that the granulocytic chalone exercises some control over the multiplication of all stem cells.

The differentiation of the lymphocytic stem cells evidently occurs in response to antigen invasion, when "the

antigen, like the (embryonic) inducer . . . commits a cell to a certain pathway of differentiation . . . among several it might have taken"<sup>25</sup>. The result of such differentiation is the production of a group of progenitor cells which undergo a series of mitoses as they mature into a group of plasma cells. These then constitute a new tissue which synthesizes the appropriate antibody and possibly also a chalone.

**Conclusions.** When for physiological reasons it is necessary to increase both the mass and the functional activity of a tissue this may be achieved by a hormone which causes an increase in the mitotic rate, or by a poietin which causes new cells to be introduced into the tissue, or by an antigen which induces the creation of a new tissue. All these reactions depend on some stimulus which commonly originates externally to the animal.

The mitogenic hormones may be target-tissue-specific because of some steric affinity with the tissue chalone which they may neutralize. It has sometimes been suggested that all tissues may be subject to this type of mitotic stimulus, but the evidence is inadequate and the proposition is doubtful.

The poietins and antigens act primarily on relatively undifferentiated stem cells to induce the final step in their process of differentiation. This is a type of mechanism which must be common to all tissues, but it is one which in mammals normally operates only in the embryo. It is evident that the homeostatic mechanisms in the lymphocytic system may be the most complex that exist in the adult mammal.

### Mitotic Homeostasis and Carcinogenesis

It is reasonable to believe that carcinogenesis is the result of some breakdown in the control of cell production and cell maturation, and that such a breakdown may be the result of damage at the nuclear or the cytoplasmic level. From the evidence given above, it is clear that any failure in the chalone mechanism would be expected to result in increased mitosis, reduced functional maturity, and a reduced life-span for any cells that were able to mature. It is well known that all these are common characteristics of tumour cells. There are several possible points at which the chalone mechanism could be damaged<sup>26</sup>, but in all cases the consequence should be either a shortage of chalone or a failure to react to whatever chalone is present.

In considering the chalone theory in relation to carcinogenesis it is unfortunately necessary, in the limited space available, to over-simplify the problem and to deal very inadequately with the relevant literature. However, a more extended statement is in preparation<sup>8</sup>. It is commonly believed that the initial damage which creates the incipient tumour cell is permanent and irreversible. Since even within the one tissue this damage may lead to very different types of tumours it is clear that it must be very variable, both quantitatively and qualitatively. However, in all cases it must include damage to the mitotic and functional homeostatic mechanism. If this results in a failure to respond to the chalone that is present, then the damaged cells would be expected to lose immediately their ability to function as part of the tissue, to commence unhindered mitotic activity, and to form a rapidly growing malignant tumour. If, however, the damage results in a failure to synthesize chalone, then nothing at all may happen since the damaged cell, being embedded in a mass of normal cells, should continue to be controlled by the chalone which it receives from these normal cells. In this way it may remain relatively quiescent for a long time. Indeed, no tumour may develop at all until, as a result of slow proliferation, the damaged cell gives rise to a group of abnormal descendant cells which is so large (perhaps about 1 mm diam.) that its central region is beyond the effective range of the inward-diffusing chalone.

The length of this period of quiescence must normally be a matter of chance, but it is evident that it should be shortened in any situation, such as adrenalectomy or tissue damage, that tends to weaken the chalone mechanism in the surrounding tissue. It is now well known that both adrenalectomy<sup>27</sup> and tissue damage<sup>28</sup> do indeed have this effect and, as would be expected, so also do the mitogenic hormones and possibly the poietins. Conversely, the period of quiescence should be lengthened by any situation, such as stress, that strengthens the chalone mechanism and, indeed, one of the most potentially significant observations in the whole history of cancer research is that in mice stressed by partial starvation the period of tumour cell quiescence may be so prolonged that cancer never develops at all<sup>29</sup>. A major effort to explain this effect in terms of diet *per se* has failed, but when it is interpreted in terms of stress it falls into line with the results obtained with other forms of stress<sup>30</sup> and with the glucocorticoid hormones<sup>27</sup>.

When the quiescent period ends, the tumour which then appears is commonly still slow-growing, and it may even come to rest at some new point of balance. In such cases the cells are able to respond, at least partially, to changes in chalone concentration or efficiency. Thus, when excess granulocytic chalone is introduced by the transfusion of fresh blood, a myeloid leukaemia may be temporarily suppressed<sup>31</sup>; when the liver chalone concentration is reduced after partial hepatectomy there is a greatly increased mitotic rate in small adenomatous nodules<sup>32</sup>; and in some tumours a diurnal mitotic rhythm may even be found<sup>33</sup>.

It also seems probable that hormone-dependent tumours must continue to react to chalones. If a mitogenic hormone exerts its effect through the specific neutralization of the tissue chalone, then an especially great mitotic reaction may be expected in any incipient tumour cells which are producing less than the normal amount of chalone. When the hormone is withdrawn such cells may still be able to produce enough chalone to reduce the mitotic rate and even to cause tumour regression, but when the hormone is restored the tumour should grow again in the same position. Such reactions are well known, for example, in the mammary gland<sup>34</sup>.

A tumour does not normally remain benign and it is common for its cells to undergo progressive changes leading to greater malignancy. When this process reaches its extreme the cells show a high mitotic rate combined with a complete inability to specialize for tissue function. In such cells there may be either a failure to produce any chalone at all or a failure to react to what chalone they do produce, and there is some evidence that both these situations may occur. Regarding the first, it has been noted that malignant leukaemic granulocytes may be unable to induce a chalone-like inhibition of lymphocyte mitosis<sup>35</sup>. Regarding the second, it has been found that other malignant leukaemic granulocytes do continue to produce a chalone-like substance capable of inhibiting mitosis in normal granulocytic progenitor cells *in vitro*<sup>4</sup>, but that they themselves are unable to respond to the chalone of normal granulocytes<sup>34</sup>.

At the moment the relevance of the chalone theory to carcinogenesis is only tentative, but it is certainly reasonable to suggest that the chances of active tumour growth, whether during or just after the period of quiescence, are likely to be significantly reduced if the normal homeostatic mechanism of the tissue is strengthened. Conversely, it is also relevant to question whether the low-stress effects of domestication and of a high standard of living may tend to promote the earlier and more frequent appearance of cancer.

### General Conclusions

It is obvious that the mechanism underlying mitotic and functional homeostasis in adult mammalian tissues

will prove to be far more complex than has been suggested here, but it will be enough if the present relatively simple theory can provide some basic insight into this difficult field and if, for a time, it can act as a useful conceptual basis on which future work can be planned. Recent years have seen great advances in biology, especially in the field of genetics, and one of the most baffling of all remaining mysteries is the phenomenon of differentiation, which begins in the embryo but which continues throughout life as part of the mitotic and functional homeostatic mechanism discussed here. In pathology, one of the most important of all problems concerns the manner in which this homeostatic mechanism may be weakened to permit the development of cancer, and in a recent critical article<sup>35</sup> it has been remarked that "it is biocybernetics, the science of organismal organisation . . . which must take over from cancer research". The problems discussed here form a basic part of this branch of science, which must become increasingly prominent in years to come.

# TEMPORARY HAIR LOSS ASSOCIATED WITH THE SLATE MUTATION OF COAT COLOUR IN THE MOUSE

By PROF. LOUIS J. PIERRO

Storrs Agricultural Experiment Station, University of Connecticut, Storrs, Conn.

AND

PROF. HERMAN B. CHASE

Biology Department, Brown University, Providence, Rhode Island

'SLATE' (*slt*), an autosomal recessive mutation in the mouse characterized by a dilution of coat colour, arose spontaneously in strain YZ57/*Ch* (ref. 1). Investigations of the effect of *slt* on coat colour indicated that it could be traced to the concentration of the melanin pigment of the hair into a reduced number of large aggregated pigment granules<sup>2</sup>. In addition to its effect on melanin pigmentation, *slt* also appeared to exert some effect on the hair growth process. The observations to be described indicated that *slt* was capable of inducing the hair follicles to lose their hairs prematurely and, in some cases, of inhibiting the initiation of the subsequent hair growth cycle.

In the mouse, as in other mammals, hair growth is a cyclic process. Hairs are produced within follicles, with periods of hair production alternating with periods of follicular quiescence. The hairs produced during a given period of follicular activity are retained within the follicles for variable periods which overlap with the appearance and growth of hairs during subsequent cycles. Older hairs, the so-called club hairs, are only gradually lost and no extensive 'moulting' process is observed. In the 'Slate' strain, which was derived from a mating between the original mutant and a normal sibling female, approximately 5 per cent of the *slt* homozygotes lost most of the dorsum hairs of the first coat during the fourth week after birth, that is, following the cessation of the first hair growth cycle. An apparently normal second coat was grown by affected animals, although the onset of the cycle appeared to be somewhat delayed in some cases. Coats of affected animals were generally normal in appearance for the remainder of the life of the animals, but in some cases the coats of older animals became somewhat sparse. Matings between animals in the original 'Slate' strain produced about the same proportion of affected progeny regardless of whether or not one or more of the parents had shown the temporary hair loss condition. That *slt* was important for the determination of the temporary hair loss condition under investigation was demonstrated by observations made when *slt* was introduced into other backgrounds.

During the course of investigations carried out in order to determine the pattern of inheritance of the coat colour dilution observed in the 'Slate' strain, as well as to test for allelism with various other pigmentation mutations, 'Slate' was mated to a number of different strains. When 'Slate' was mated to *CT/Ch*, a male which showed a rather extreme expression of the temporary hair loss condition was recovered in the  $F_2$  generation. This animal was homozygous for maltese dilution (*d*) as well as for *slt* and heterozygous for pink-eye (*p*) and for brown (*b*). Its coat appeared normal until early in the third month, when all the hairs on its dorsum were lost. The animal did not grow a new coat of hair until five months later. From the  $F_2$  of the cross between 'Slate' and *CT/Ch* four separate stocks of mice were set up. These stocks were homozygous for *p*, *pd*, *d slt* (*DSLTL*) and *p d slt* (*PDSLTL*), respectively. All stocks were continued by brother-sister matings for at least four generations, but the hair loss characteristic was observed only in two stocks, *DSLTL* and *PDSLTL*.

The *DSLTL* stock was initiated by mating the affected  $F_2$  male described here to a non-sibling  $F_2$  female. This mating produced one male which also lost the club hairs from his dorsum during the third month. When this male was bred to his normal sibling sisters some variation of the temporary hair loss trait was observed in 40 per cent of the offspring ( $N = 35$ ). Of the affected progeny, two were *d slt*, seven were *d b slt*, and five were *p d slt*. In the *d slt* animals, hair loss was observed during the third month, that is, following the end of the second hair growth-cycle. This was later found to be characteristic for affected *d slt* mice. The amount of hair lost varied, however. In some affected individuals only denuded patches were found; in others, loss of hair was virtually complete except for the head region. In all affected *d slt* animals, there was an accompanying inhibition of the succeeding hair growth cycle. Inhibition lasted for as long as a year in some cases; in others, it involved only the suppression of a single hair growth cycle. The expressions of the temporary hair loss condition in *d b slt* and in *p d slt*, to be described in the next section, were similar to one another, but differed markedly from that observed in *d slt*.

Three subsequent generations of brother-sister matings using *d slt* mice produced only *d slt* progeny, and the incidence of the hair loss condition averaged 6.5 per cent. For none of these matings were affected male and female siblings available, but all other mating possibilities were represented. No differences in incidence of the trait were observed between matings involving two normal animals, or an affected male with an unaffected female (Table 1). Matings between unaffected males and affected females produced a greater proportion of affected progeny, but the difference was not significant ( $\chi^2 = 2.75$ ,  $P = 0.10$ ). Matings between two affected non-siblings were also set up, and these produced 50 per cent affected progeny. However, of the nine affected animals only five were *d slt*, the remaining four were *d b slt*.

In all the matings listed in Table 1, a substantial number of progeny failed to survive long enough to be fully classified, that is, until the third month. Mortality was especially high in crosses involving affected males and females and, coupled with the low productivity of the matings, quickly frustrated attempts to continue the stock by mating affected animals. The majority of the deaths occurred during the third week after birth. Moribund animals were extremely emaciated in appearance. Necropsy examination showed that the caecum was distended and filled with extremely dry solid matter, suggesting the condition megacolon. A similar condition has been found to be associated with piebald-lethal<sup>3</sup>, and, although this particular allele was not known to be

Table 1. INCIDENCE OF THE TEMPORARY HAIR LOSS TRAIT IN STRAIN *DSLTL*

All animals classified at the age of 3 months				
Mating type	No. of litters	No. of progeny	No. classified	Affected animals (%)
$N\delta \times N\delta$	12	82	50	4.0
$A\delta \times N\delta$	11	81	43	4.6
$N\delta \times A\delta$	11	80	73	9.0
$A\delta \times A\delta$	5	39	18	50.0

*N*, normal; *A*, affected.

Table 2. INCIDENCE OF TEMPORARY HAIR LOSS TRAIT IN STRAIN *PDSLT*

Generation	Mating type	No. of litters	No. of progeny	No. classified	Affected animals (%)
$F_1 \times F_1$	$N \times N$	5	39	11	0.0
I	$N \times N$	7	48	31	9.7
II	$A \times A$	4	29	26	85.4
III	$A \times A$	4	23	22	77.3
IV	$A \times A$	4	33	17	94.1

N, normal; A, affected.

present, piebald (*s*) had been introduced by 'Slate' and was segregating in the crosses. However, not all the moribund animals were homozygous for *s* and, conversely, not all the animals homozygous for *s* became debilitated and died.

As already indicated here, the temporary hair loss condition was also observed in a stock homozygous for *p*, *d* and *slt* (*PDSLT*). (The brown allele (*b*) had also been introduced into the stock by *CT/Ch*, and was segregating in the stock but could not be reliably detected except by genetic test because of the extremely light pigmentation of the coat of the *p d slt* animals.) Affected animals were observed in the very first mating involving full sibs, and the proportion quickly increased to 94 per cent within a few generations of selective inbreeding of full sibs (Table 2). These results indicated that, given a certain amount of genetic heterozygosity, selection could be effective in increasing the number of animals which showed the temporary hair loss condition. The rapidity with which selection approached 100 per cent expression suggested that interaction between *slt* and only a small number of genes was responsible for the gains observed. It seemed possible that much of the gain was associated with an increase in the frequency of *b* in the stock. Most of the animals tested in generation IV were homozygous for *b*, although some affected animals carried the black (*B*) allele.

All affected animals exhibited a temporary hair loss condition during the third week. It involved a random thinning of the coat. This condition, reminiscent of that reported for the mutant gene alopecia<sup>4</sup>, was characteristic for hair loss in all *p d slt* and *d b slt* animals. It was often followed by a short lag in the initiation of the second hair growth-cycle, and it was repeated in some cases after cessation of the second cycle. It usually did not recur after this time.

As in the case of the *DSLT* stock, mortality was also rather high in *PDSLT*. In some cases the deaths occurred during the third week, and the symptoms resembled those encountered in the *DSLT* strain. In addition, a number of animals in *PDSLT* died early in the second month. These were usually affected animals which lagged behind their litter-mates in the onset of the second hair growth-cycle. In each *PDSLT* litter one or two of the affected animals lagged behind the others in growth rate and in the replacement of the coat. These animals either died or, if they survived, they always remained considerably smaller than their litter-mates.

A temporary hair loss condition resembling in some particulars the trait observed in 'Slate' has been a common observation in a small percentage of individuals in various *C57* 'Black' sub-strains. Since the *YZ57/Ch* strain in which the *slt* mutation originated was derived in part from *C57* 'Black'/*10Ch*, one possible explanation for the temporary hair loss condition was that it had a genetic basis in common with that responsible for the hair loss condition in *C57* 'Black' sub-strains. (Occasional animals which showed a temporary hair loss condition had been seen in *YZ57/Ch* prior to the origin of the *slt* mutation, although detailed data on the occurrence of the condition in the strain were not available.) Crosses between 'Slate' and *C57* 'Black'/*10Ch* failed, however, to produce any individuals showing the temporary hair loss trait in either  $F_1$ ,  $F_2$  or first back-cross generations. Affected animals from Generation IV in the *PDSLT* strain (94 per cent affected) were also crossed reciprocally with *C57* 'Black'/*10Ch*, and these crosses similarly did not produce any

affected progeny in either  $F_1$  or  $F_2$  generations (102 and 89 progeny classified, respectively). Four affected individuals were observed in back-crosses to *PDSLT*, however, even though only a relatively small number of animals (55) were classified. Three of these were *p d slt*; the other was *d b slt*. These results indicated that the temporary hair loss condition associated with the presence of *slt* could not be attributed solely to the partial derivation of the *YZ57* strain from a *C57* 'Black' sub-strain.

The foregoing observations suggest that: (1) a temporary hair loss condition may result as a second consequence of the presence of *slt* in the homozygous condition; (2) the expression and incidence of the hair loss trait are subject to modification by the presence of what is probably a small number of additional genes. It is possible that *p*, *d* and *b* are the principal interacting genes disclosed by the present observations, or that any or all of these simply serve as markers for closely linked genes which are actually operative. The relative contributions of the various modifying genes remain a question, but there is some reason to suspect that *b* and/or closely linked genes exert a greater effect than do modifying systems marked by *d* or *p*. The possibility that much of the increase in incidence of hair loss in the *PDSLT* stock could be associated with an increase in the frequency of *b* in the stock has already been mentioned. Moreover, every *d b slt* animal encountered during the course of the development of strain *DSLT* showed the temporary hair loss trait. The same could be said for every *p d b slt* animal detected in strain *PDSLT*, although not every animal in the strain was tested genetically. It should be noted, however, that a small number of matings made between *d b slt* animals did not produce only affected progeny, and that matings between 'Slate' and *C57* 'Brown' did not produce any affected progeny in  $F_1$ ,  $F_2$  or back-cross generations. Clearly interaction between *slt* and the modifying system marked by *b* can only account for a part of the observations reported here.

A number of mutations resulting in the temporary loss of the coat and at least in some cases inhibition of replacement are known. Alopecia (*Al*), a temporary but repeated hair loss condition which is inherited as a dominant character<sup>4</sup>, has already been mentioned. Others which have been reported include: hypotrichosis juvenilis<sup>5</sup>, hypotrichosis periodique<sup>6</sup>, furless<sup>7</sup> and tufted<sup>8</sup>. Hypotrichosis juvenilis is a temporary condition which involves only the first coat, and which is inherited as a simple recessive<sup>5</sup>. Hypotrichosis periodique, a condition which shows variable expressivity but may involve loss of subsequent coats as well as the first, apparently is due to an incompletely penetrant recessive mutation<sup>6</sup>. In the case of furless, the vibrissae and hairs of the first coat are shortened, and hair loss begins during the third week<sup>7</sup>. A second coat is grown which is also shed and the animals then remain furless. In the case of tufted, on the other hand, continuous cycles of hair loss and replacement are encountered<sup>8</sup>. The first coat begins to be lost during the fourth week. It is replaced by a second coat, which then falls out, and so on. The loss-replacement cycle appears to be stopped only during pregnancy and lactation. No attempt has been made to determine possible relationships between *slt* and these mutations which appear to have as their most striking aspect an effect on the hair growth-cycle.

## LETTERS TO THE EDITOR

## RADIO ASTRONOMY

## Spectrum of the Galactic Radio Emission

A NEW series of observations of the galactic radio emission has been conducted at the frequencies of 20, 30 and 85 Mc/s. These low-resolution observations made with scaled aerials were intended to investigate the spectral index of the galactic radio emission in the frequency region 10–100 Mc/s.

The aerials used in the present experiments were in each case a folded dipole suspended above a continuous reflecting screen laid out on the ground. The height of the folded dipole above the screen was a quarter wavelength. The reflecting screen made of chicken mesh was a wave-length square in area. This disposition of the aerial allowed the observation of one declination,  $\delta = -34^\circ$ . This is quite satisfactory, since at this declination the galactic centre, regions of the galactic halo, and the southern galactic pole can be seen in the aerial beam at different times. Thus it was possible to measure sky brightness temperatures from the directions of galactic centre and different halo regions. Sky temperatures were calibrated in terms of matched temperature limited noise diodes. The noise diodes were initially calibrated against thermal loads. The receiving system was a switched radiometer with a synchronous demodulator. Narrow bandwidths were used, scaled with the frequencies. With a one second time constant a good signal-to-noise ratio was obtained at each frequency.

All the observations were taken by an observer who calibrated the receiver, adjusted matching and monitored interference. The calibration consisted of replacing the aerial by a noise diode, and under matched conditions noting the noise diode current required for the particular aerial temperature deflexion. Occasional man-made interference was encountered during the observations. This interference was most common in the daytime. At the frequency of 20 Mc/s besides man-made interference sporadic daytime absorption was observed. This seems to be associated with the sporadic *E* layer in the ionosphere. During the night observations are unhampered by ionospheric effects since the ionospheric critical frequency  $f_o F_2$  was less than 5 Mc/s during the observing period March–September 1964.

The results obtained consist of sky brightness temperatures for the declination  $\delta = -34^\circ$  at the frequencies of 20, 30 and 85 Mc/s. At the frequency of 20 Mc/s some eight hours of readings could not be obtained at present. However, most of the halo region has been measured at this frequency. The sky brightness values are accurate to  $\pm 7$  per cent. This error is made up of individual contributions due to the r.m.s. noise, residual cable losses and day-to-day variations. The results at different frequencies were compared with information obtained on the value of the temperature spectral index (the usage of the spectral index  $\beta$  follows Turtle *et al.*<sup>1</sup>, that is,  $T \propto \lambda^\beta$ ). In addition our present results can be compared with those obtained by other observers.

In the frequency range 20–85 Mc/s the spectral index is found to be  $\beta = 2.6 \pm 0.2$ . This value is found by comparing the observed sky temperatures at a number of points in the direction of the galactic halo.

In the frequency region 30–85 Mc/s the spectral index is found to be  $\beta = 2.63 \pm 0.07$ . This value of spectral index is deduced from a complete scaled aerials experiment. This experiment involves the measurement of sky temperatures at many points in the direction of galactic halo

and comparing the observed temperatures. Fig. 1 shows the results of the scaled aerial experiment. A similar comparison in the frequency range 20–30 Mc/s is not yet possible because of lack of the necessary observations.

Following the calculation of the values of the spectral index we compared our present observations with those of other observers. Great caution is required in such a comparison since the different aerial systems used by each observer may lead to erroneous conclusions. We have collected most of the recently published results in the frequency range 1–404 Mc/s. The sky temperatures reported were converted to brightness values and plotted against frequency as shown in Fig. 2. These values in each case were for observations near the direction of the southern galactic pole. The results in the frequency range 1–10 Mc/s were taken from Ellis<sup>2</sup>, and include ground-based, rocket and satellite observations. The result at 18.3 Mc/s was plotted directly from the map given by Shain and Higgins<sup>3</sup>. The four points taken from Turtle *et al.*<sup>1</sup> were averaged over ten beamwidths near the direction towards the south galactic pole. Near the frequency of 85 Mc/s a number of results was available. That of Mills<sup>4</sup> was obtained with a narrow beam aerial and thus as expected falls below the other points. The 81.5-Mc/s result obtained by Purton<sup>5</sup> was treated in the same manner as the other points of Turtle *et al.*<sup>1</sup>. Our own results at 20, 30 and 85 Mc/s are also shown in

Fig. 1. Comparison of sky temperatures at 30 and 85 Mc/s

Fig. 2. Collected observations of sky brightness in the frequency range 1–404 Mc/s

Fig. 2. Rather surprisingly, results obtained with different aerial systems fit in well, with a few exceptions, in the whole frequency range of 18.3–404 Mc/s. Over this very large frequency range the spectral index is calculated,  $\beta = 2.65 \pm 0.15$ . Furthermore the shape of the spectrum can best be interpreted to be a straight line with no turnover point down to the frequency of 18.3 Mc/s.

Further observations are planned at a frequency near 10 Mc/s as well as a new scaled aerial series with improved resolution.

## PHYSICS

### Fields of Moving Multipoles

IN free space the electromagnetic potential  $\varphi^\mu$  of Maxwell's equations is related to the sources of the field  $j^\mu$  by the equation  $\square\varphi^\mu = j^\mu$ . If the source of the field is an arbitrarily moving charge, the retarded solution for  $\varphi^\mu$  may be expressed as an integral over the world line of the charge ( $z^\mu = z^\mu(\tau)$ ):

$$\varphi_{\text{ret}}^\mu = 4\pi e \int_{-\infty}^{\infty} \dot{z}^\mu(\tau) D_{\text{ret}}(x - z(\tau)) d\tau \quad (1)$$

where  $D_{\text{ret}}$  is the four-dimensional retarded Green's function. Concise expressions for the fields  $F^{\mu\nu} = \varphi^{\mu,\nu} - \varphi^{\nu,\mu}$  can then be obtained by differentiating under the integral sign in (1). The same processes may be applied to the calculation of the radiation fields  $F_{\text{rad}}^{\mu\nu} = F_{\text{ret}}^{\mu\nu} - F_{\text{adv}}^{\mu\nu}$  (by changing the Green's function) and the method affords an effective means of evaluating the radiation field on the world line of the charge<sup>1</sup>. The latter fields have the value:

$$F_{\text{rad}}^{\mu\nu}(z(0)) = \frac{4}{3} e [\dot{z}^\mu \ddot{z}^\nu - \dot{z}^\nu \ddot{z}^\mu] \quad (2)$$

Recent work<sup>2</sup> has shown how these processes may be extended by methods of induction to arbitrarily moving electromagnetic multipoles. By integrating by parts successively until the Green's function emerges undifferentiated in the integrands and then carrying out the integration, concise and explicit expressions have been obtained for the potentials and fields of a generally moving  $2^m$ -pole. When  $m = 1$  the expressions for the fields bear full agreement with those recently found by G. N. Ward<sup>3</sup> for a dipole. By expanding the integrand as a power series in  $\tau$  the radiation fields have been calculated for a point  $x^\mu = z^\mu(0)$  on the world line of the dipole. An interesting special case has been studied when the moment vector of an electric dipole undergoes Fermi-Walker propagation along the world line of the motion. This represents in a relativistic way the notion of a non-rotating dipole. It has been found that the radiation field measured along the world line vanishes for hyperbolic motion in particular, and in general only if the dipole centre suffers constant acceleration ( $\ddot{z}^\mu \dot{z}_\mu = \text{const.}$ ). A parallel can be

drawn here with an accelerating charge. The expression (2) also vanishes for hyperbolic motion.

Although it is not known whether the derived radiation fields for a moving dipole are continuous with the values at events not lying on the world line, they are certainly continuous along it, and for moving  $2^m$ -poles in general, the world line radiation is finite only so long as  $m \leq 4$ , that is, for singlets, dipoles, quadrupoles, octupoles and  $2^4$ -poles. When  $m > 4$ , this radiation is apparently infinite. The radiation potential  $\varphi_{\text{rad}}^\mu$  satisfies the homogeneous equation  $\square\varphi^\mu = 0$  everywhere; however, the method used for evaluating the field gives rise to a singularity along the world line. This singularity in  $\square\varphi_{\text{rad}}^\mu$  is removable (finite) when  $m \leq 3$ , but when  $m > 3$  it is non-removable there (infinite). It seems worth mentioning that the situation could in some way be a reflexion on the number 3 of spatial dimensions, in the non-degenerate construction of infinitesimal multipoles by means of rigidly connected charges<sup>4</sup> according to the progression: rod, parallelogram, parallelepiped, where alternating charges occupy the positions of adjacent vertices.

### Upper Limits on Galactic Cosmic Ray Antiproton Intensities

KNOWLEDGE of the abundance of antiprotons in cosmic rays and in interstellar space could have important implications for cosmic ray theory,  $\gamma$ -ray astronomy and certain cosmological theories. For these reasons, attempts have been made both experimentally to measure the intensity of antiprotons in cosmic radiation and theoretically to estimate what antiproton densities might be expected in space. A recent communication<sup>1</sup> by Brooke and Wolfendale, which stimulated the calculation presented in this communication, has placed an experimental upper limit of about 5 per cent on the concentration of antiprotons ( $\bar{p}$ ) in the primary cosmic radiation near the Earth with energies of the order of 1,000 GeV.

For theoretical estimates, the sources of  $\bar{p}$  which have been proposed are: (a) primeval, (b) continuous creation, (c) cosmic ray collisions. The first two are speculative, but the third source can be estimated. In a previous calculation<sup>2,3</sup> of the production of antiprotons in the galaxy by collisions of cosmic rays with interstellar gas, Fradkin used the Fermi statistical model of high-energy nucleon-nucleon collisions, assumed a power law spectrum for the  $\bar{p}$  produced, and assumed that the antiproton lifetime in the galaxy was limited by annihilation. The calculations gave upper limits of 0.05 per cent<sup>3</sup> and 0.04 per cent<sup>2</sup> for the relative concentration of  $\bar{p}$  in cosmic radiation having total energies greater than 1.7 and 9.3 GeV respectively. More recently, without giving details, Hayakawa<sup>4</sup> estimates about  $10^{-4}$  for the ratio of antiprotons to protons in galactic cosmic rays.

In the light of more recent laboratory measurements of proton-proton collision cross-sections, and emulsion measurements of the mean amount of interstellar matter traversed by cosmic ray nuclei, it is possible now to improve the basis on which the earlier theoretical estimates of galactic antiprotons were made, although these improved estimates cannot be compared directly with the measurements of Brooke and Wolfendale. We consider here the production of antiprotons in the reaction:

due to the primary cosmic radiation incident on the interstellar or intergalactic hydrogen or helium. Other reactions generating  $\bar{p}$ , such as collisions of cosmic ray protons, antiprotons, or nuclei with interstellar hydrogen, helium, etc., and  $\bar{p}$  generation via intermediate  $\bar{n}$  production, can be neglected within the accuracy of the present calculation. The removal of antiprotons that are created in the galaxy can occur by  $\bar{p}-p$  annihilation within the galaxy and by escape from the galaxy into intergalactic space. Thus, assuming a steady state in the galaxy for the cosmic rays and antiprotons, the antiproton density in the galaxy is given approximately by:

$$\bar{n} = \bar{q} T_{\text{eff}}, \quad T_{\text{eff}}^{-1} = T_{\text{ann}}^{-1} + T_{\text{esc}}^{-1} \quad (2)$$

where  $\bar{n}$  is the number density of  $\bar{p}$   $\text{cm}^{-3}$ ,  $\bar{q}$  is the volume production rate of  $\bar{p}$   $\text{cm}^{-3} \text{sec}^{-1}$ , and  $T_{\text{eff}}$ ,  $T_{\text{ann}}$ ,  $T_{\text{esc}}$  are, respectively, the effective, annihilation and escape lifetimes of a  $\bar{p}$  in sec, corresponding to free paths of  $L_{\text{eff}}$ ,  $L_{\text{ann}}$ , and  $L_{\text{esc}}$  g  $\text{cm}^{-2}$ . For simplicity, the 'galactic model' of the origin of cosmic rays is used here<sup>5</sup>.

To find  $\bar{q}$  we use the following:

$$\bar{q} = \int_{E_T}^{\infty} n_p \sigma(E) j(E) dE \sim n_p \bar{\sigma} J(E_T) \quad (3)$$

where  $j(E)dE$  is the differential and  $J(E)$  the integral energy spectrum of primary cosmic radiation (omnidirectional values),  $n_p$  is the galactic hydrogen density,  $\sigma(E)$  is the cross-section for reaction (1) and  $E_T \approx 6$  GeV is the laboratory kinetic energy threshold for reaction (1). Experimentally, we know the cosmic ray spectrum above 6 GeV near the Earth quite well<sup>6,7</sup>, while estimates of the gas or hydrogen density in the galaxy are: an average of 0.7 protons  $\text{cm}^{-3}$  in the disk, and an upper limit of  $10^{-2} \text{ cm}^{-3}$  in the halo<sup>8</sup>.

However, information about the cross-section  $\sigma(E)$  is fragmentary. Theoretical estimates<sup>9-11</sup> give a  $9/2$  power dependence on the  $C.M.$  kinetic energy of the incident proton for  $\sigma(E)$  but are limited to the energy region near threshold, and by lack of an accurate value for the coupling constant. Experimental data bearing directly on the cross-section for reaction (1) are limited partly by the fact that it is one of many competing open channels. However, laboratory measurements at an incident proton momentum of 19 GeV/c give cross-sections for (1) of  $0.09 \pm 0.025$  and  $0.05 \pm 0.011$  mb  $\text{sr}^{-1} (\text{GeV}/c)^{-1}$  for  $\bar{p}$  recoil momenta of 3.35 and 4.6 GeV/c, respectively, at a laboratory angle of 116 mrad<sup>12</sup>. At higher energies more channels become available but the total inelastic cross-section seems to remain constant at about 20 mb, probably implying a decrease in the cross-section for any particular channel. One can place upper limits on the  $\bar{p}$  production cross-section at various energies by considering data<sup>13,14</sup> giving the total inelastic cross-sections for  $p-p$  scattering up to a few hundred GeV, and the percentages  $W_{\frac{1}{2}}^{\pm}$  of the inelastic events having charged four-pronged products.  $W_{\frac{1}{2}}^{\pm}$  is typically about 0.5 at 6 GeV, 0.3 at 27 GeV and the corresponding inelastic cross-sections,  $\sigma_{\frac{1}{2}}(E) = W_{\frac{1}{2}}^{\pm} \sigma_{\text{inel}}^{\text{tot}}(E)$  are about 11 mb and 7 mb. These values could be perhaps some orders of magnitude larger than  $\bar{\sigma}$  for  $\bar{p}$  production since many of the four charged prong channels in  $p-p$  scattering at these energies lead to pion production. In the region 6–10 GeV, where the cosmic ray beam is strong, since  $\sigma(E_T) = 0$ ,  $\bar{\sigma} < \sim 5$  mb.

Using these values in equation (3), assuming that the local cosmic ray intensity is typical of that in the galaxy, and using the estimate that the total mass of the interstellar gas in our galaxy contains about  $2 \times 10^{68}$  protons, the total  $\bar{p}$  production rate in our galaxy is then  $< \sim 2 \times 10^{68} \times (5 \times 10^{-27}) \times 1$ , that is,  $\leq 1 \times 10^{40} \text{ sec}^{-1}$ .

The quantities required to evaluate equation (2) for the  $\bar{p}$  density are found as follows: the cross-section for  $\bar{p}$

annihilation is the same as the inelastic  $\bar{p}-p$  cross-section, about 50–110 mb, for antiproton kinetic energy below 0.3 GeV (ref. 15). For  $\bar{p}$  kinetic energies of 0.5–1.2 GeV the inelastic  $\bar{p}-p$  cross-section, which is mainly annihilation, is roughly constant at about 60 mb (ref. 15), and seems to remain at this value at 2 GeV (ref. 13), falling to 37 mb at 12 GeV (ref. 16). These give  $T_{\text{ann}} \approx 1 \times 10^{18}$  sec in the disk, and  $1 \times 10^{17}$  sec in the galaxy as a whole. To find the escape time, we use the value of about 3 g  $\text{cm}^{-2}$  for the amount of matter traversed by cosmic ray nuclei from source to solar system<sup>4</sup>; this value will be assumed as the escape distance for antiprotons as well:  $L_{\text{esc}} = 3$  g  $\text{cm}^{-2}$ . Thus, the escape time is  $T_{\text{esc}} \approx 1 \times 10^{14}$  sec,  $> \sim 1 \times 10^{10}$  sec, if the  $\bar{p}$  spends most of its galaxy lifetime in the disk, or the halo, respectively. Under either of these conditions,  $T_{\text{esc}} < T_{\text{ann}}$  in the galaxy, so  $T_{\text{eff}} \approx T_{\text{esc}}$ .

From equations (2) and (3),  $\bar{n}/n_p = \bar{\sigma} J(E_T) T_{\text{eff}}$ , or:

$$\frac{\bar{p}}{p} \equiv \frac{J\bar{p}(0)}{J(0)} = \frac{\bar{\sigma} L_{\text{eff}}}{m_p} \frac{J(E_T)}{J(0)} = \frac{\bar{\sigma}}{\sigma_{\text{esc}}} \frac{J(E_T)}{J(0)} \quad (4)$$

where we have introduced an 'escape cross-section',  $\sigma_{\text{esc}} \equiv m_p/L_{\text{esc}}$ , where  $m_p$  is the proton mass, and  $L_{\text{eff}} \approx L_{\text{esc}} = 3$  g  $\text{cm}^{-2}$ , giving  $\sigma_{\text{esc}} \approx 500$  mb. With  $\bar{\sigma} < 5$  mb, equation (4) gives  $\bar{p}/p < \sim 3 \times 10^{-3}$ .

Since the effective  $\bar{p}$  production cross-section is expected to be considerably smaller than 5 mb, these calculations indicate that the  $\bar{p}$  fraction of the galactic cosmic ray beam integrated over all energies is expected to be considerably less than 0.3 per cent.

Because our estimate is for galactic  $\bar{p}$ 's of relatively low energies, while Brook and Wolfendale's measurement is for high-energy  $\bar{p}$ 's near the Earth, it is not possible to compare our theoretical limit directly with Brooke and Wolfendale's measured limit.

In the future, improved laboratory cross-section data will enable more accurate calculations of the low-energy  $\bar{p}$  intensity to be made. This, subtracted from the low-energy  $\bar{p}$  intensity measured in space, would yield an intensity difference presumably due to low-energy  $\bar{p}$ 's produced primevally or by continuous creation (Brooke and Wolfendale, private communication).

A promising observational technique for placing upper limits on  $\bar{p}/p$  is to expose nuclear emulsions to the primary cosmic rays by means of satellites. In this way, Grigorov *et al.*<sup>17</sup> find an upper limit of 0.1 per cent for the ratio of cosmic ray anti-nuclei to nuclei having  $Z > 2$  at an altitude of 300 km. Since these measurements were for stopping particles the energies involved are probably less than some few hundred MeV.

$\gamma$ -Ray measurements could also give indirect experimental information on the galactic antiproton intensity, since some antiproton annihilations eventually produce  $\gamma$ -rays, but the usefulness of this method is severely handicapped by the number and nature of the competing processes.

By using the Kraushaar and Clark<sup>18</sup> measured upper limit on the cosmic  $\gamma$ -ray intensity, astrophysical data<sup>19</sup>, and  $\bar{p}$  annihilation cross-sections<sup>20</sup>, the following approximate upper limits on  $J\bar{p}$  in  $\bar{p} \text{ cm}^{-2} \text{s}^{-1}$  can be estimated: 1–100 in interstellar space, depending on direction, 30 in the Crab Nebula, and 0.1–1 for intergalactic space. Unfortunately these limits appear to be too large to be useful.

In summary, estimates based on recent cross-section data indicate that the low-energy  $\bar{p}$  fraction of the cosmic ray beam is probably much less than 0.3 per cent. The estimates will be refined considerably when antiproton total and differential production cross-sections become available.

We thank Dr. V. L. Ginzburg and Dr. D. ter Haar for sending an advance copy of ref. 5, Mr. G. Brooke and Dr. A. W. Wolfendale for their advice concern-

ing the manuscript, and Dr. H. Muether, Dr. R. H. Phillips and Dr. R. Hagedorn for their communications.

### Surface Gas Eruption and Van der Waals Cohesion on Tungsten

IN some experiments on the detection of single atoms and molecules reported earlier<sup>1</sup>, it was noticed that, in the early stages of the conditioning of the point, there were occasions when, on increasing the field by some 20 per cent, an abrupt instability in the field current occurred; this invariably produced excessively large currents. The field emission pattern of the emitting facets of the point, previous to this, was, of course, badly blurred, with no definition comparable with that from clean points, but it was possible to discern 'out of focus' non-emitting areas on the fluorescent anode; as soon as the instability arose, there was complete loss of resolution, and the pattern showed a uniform streaming as if a sheet of gas was moving across the point. When the point had been fully 'conditioned', it required a much higher field to produce the effect. If, however, the whole vacuum system was let down to air at atmospheric pressure and soon after pumped out, it was possible to obtain repeated gas eruption and current instability without further increase of field.

We have in this simple observation a method of determining the Van der Waals cohesion of the topmost atoms in a multilayer gas film on tungsten. The effect of the field,  $E$ , is to polarize the adsorbed gas layer and put a strain on the film; the force on a single atom  $\alpha E dE/dz$  where  $\alpha$  is its polarizability works out at  $\sim 1/10^{12}$  newtons. This tensile force acts in the presence of a random positive ion bombardment of the point by molecular and atomic ions of oxygen, nitrogen, carbon monoxide and carbon at a rate of about 500/sec; the recovery time of the surface may have values up to and beyond 1 msec.

The random nature of the bombardment is shown in Fig. 1(a), where it is seen that the interval between successive ion impacts may lie within the recovery time of the surface; when this happens, the surface gas is violently disturbed, the field current rises abruptly, and it may take several msec for the surface to come to a stable equilibrium. This behaviour is consistently repeatable on letting the system down to air and re-pumping; it must result in the stripping off of the topmost loosely held gas layer (or layers). An excellent example of the fluctuating currents caused by three impacts within the recovery time of the surface is shown in Fig. 1(b).

Fig. 1

A value for the cohesive energy of the gas can be derived by considering the momentum of the impacting particle to be shared between the gas and the tungsten/oxide substrate, according to their binding energies  $B_g$  and 10 eV, respectively. At 2 kV the incoming momentum is proportional to  $1.6 \times 10^7$ , so that  $1.6 \times 10^7 B_g / 10 \times 10^7$  represents the velocity taken up by the gas, as a unit, since there are approximately  $10^7$  atoms on the sensitive surface of the point. An average recovery time of 1 msec corresponds to gas moving over the linear dimensions of the point,  $10^{-5}$  cm, with a velocity of  $1/10^2$  cm/sec, hence  $B_g \sim 1/16$  eV per atom. This value is in reasonable agreement with that calculated by London for the Van der Waals energy for molecular crystals of oxygen as given in Seitz—1.69 kcal/mole.

It is interesting to note that an oxygen ion at a distance of 10 Å from the tip would have a field of  $10^8$  V/M associated with it and would act on a single surface atom with a force of the same order as that of the external field. The ensuing field emission and neutralization of the ion by an electron from the conduction band of the semiconducting tungsten/oxide contact should result in an Auger transition involving the emission of a secondary electron into the gas.

## GEOPHYSICS

## Palaeomagnetic Dating of some Younger Dikes in Southern Norway

THE occurrence of several localities of younger basic dikes in southern Norway has aroused considerable geological interest in the past. The dikes are especially common in the coastal districts between the Permian Oslo graben and the schists of the Stavanger area. Their absolute age has remained unknown, but a connexion with the Permian igneous activity in the Oslo area has been proposed<sup>1,2</sup>. Nevertheless, radioactive dating of younger Norwegian dikes has hitherto not been carried out. On this background a systematic palaeomagnetic study of the younger dikes in Norway has been undertaken by me, assuming it to be a useful tool for absolute as well as relative age determinations. So far only the extensive swarms of dolerites in the anorthosite rock complex in Rogaland have been investigated and in this communication the results are summarized.

The dolerite swarms trend west-north-west over long distances with vertical attitude reaching a maximum thickness of about 90 ft. They cut all other rocks, but where they intersect prominent fault zones slight displacements of a few feet due to later movements can be observed<sup>3</sup>. Antun, who mapped altogether 11 dikes and numbered them 1-11 from north to south, has petrographically classified the rocks into three types: trachydolerites (1-5), dolerite (6) and porphyritic dolerites (7-11). They are all olivine-bearing. Chilled margins are typical and glassy stringers are present both in margins and in apophyses. The consolidation must have been very rapid, and because of the multiple nature of the dikes Antun concludes that the intrusion act of the system must have been of short duration. Of special interest for the present investigation are the generally unaltered state of the minerals, but in the trachydolerites Nos. 1, 2, 4 and 5 some subordinate magnetite occurs as a by-product of decomposed iron-rich olivines. According to Antun the ore minerals are ilmenite and a titanomagnetite containing submicroscopic lamellae of the former.

The remanent magnetism of 44 hand samples in all has been investigated. Twenty-four samples behaved palaeomagnetically very satisfactorily. Two sites (7 samples) were obviously more or less affected by lightning. The remaining samples mostly showed internal scattered directions of natural remanent magnetism, which became either more unstable after heat treatment, or were so weakly magnetized that for practical reasons cleaning was not carried out. But even if all samples are included, the main conclusion of this investigation is not altered. So far as rocks with stable components are concerned, the results may be summarized as follows:

(1) In all dikes tested (except No. 2, where the collected site was affected by lightning) samples were found which either did not change their direction of natural remanent magnetism at all when thermally demagnetized at high temperatures, or merely contained smaller amounts of viscous magnetization which were easily removed by thermal cleaning.

(2) In the porphyritic dolerite dikes and in the dolerite dike the within-dike scatter is small. The trachydolerites, except dike No. 3, showed somewhat more scattered results probably due to the presence of the secondary magnetite mentioned above.

(3) The patterns of thermal decay of natural remanent magnetism and artificial thermo-remanent magnetism respectively are very similar for stable rock specimens, especially above 300° C.

(4) The Curie point temperature is always that for pure magnetite or slightly lower.

(5) Within an experimental error of a few degrees the directions of artificial thermo-remanent magnetism are coincident with the applied field.

Fig. 1. Stereographic projection showing dike mean directions of younger dolerites in Rogaland, southern Norway. Only samples with stable magnetic components are included. Plots are north-seeking poles in lower hemisphere (normal). Numbers are according to Antun's numeration of the dikes. Dikes No. 4 and 5 are identical, representing a bifurcating fissure, and are therefore treated together. Dikes No. 9 and 11 are not collected. x, present field direction; ⊗, theoretical dipole field direction

(6) The stable remanent directions are mostly definitely different from that of the present Earth's field.

(7) There seems to be some connexion between magnetic directions and petrography, but more sampling is needed to clarify fully this suggestion.

(8) The intensities of artificially produced thermo-remanent magnetism are of the order of  $10^{-3}$ - $10^{-2}$  E.M.U. c.c., and therefore much less than is required, in certain cases, for a stable component anomalously magnetized in the plane of the dike<sup>3</sup>.

From the experimental evidence given here it is probably reasonable to assume that the stable component of remanent magnetism of the younger dolerites in Rogaland, southern Norway, is of thermal origin (originating when the dikes cooled), and has been preserved throughout the history of the rocks and thus contains information about the Earth's field during the time of formation of the dike system. Few time-readings of the geomagnetic field seem to be incorporated in the palaeomagnetic results, and the total span of time represented is probably considerably less than the period of secular variation. The geological indications of a short duration of the whole intrusion act are therefore probably verified.

Since the deduced palaeomagnetic field directions are representative of a geomagnetic field of fairly recent origin (Cenozoic), the considered dolerites are assumed to be of Tertiary age.

In addition, preliminary results from some other dikes from nearby districts south of Bergen seem to give the same conclusion concerning age. Prior to the present investigation, but on guess work only, a theory had been put forward in favour of Tertiary rocks in Norway.

In Tertiary times crustal unrest was characteristic of the North Atlantic region. The Scandinavian landmass must have been uplifted along fault lines in the western areas at this time<sup>4</sup>, and in Sweden and Denmark there is proof of Tertiary volcanic activity. Granulometric investigations of volcanic ash layers (Eocene) in Denmark<sup>5</sup> suggests an eruption centre in Skagerak or southern Norway. Aeromagnetic surveys over the Skagerak region

in 1962 and 1963 (carried out by the Geological Survey of Norway for the University of Bergen) have shown that a rather large magnetic anomaly exists south of Kristiansand: remnants of a possible tertiary volcanic centre are perhaps localized there.

## GEOLOGY

### Age of the Transition in the Pre-Cambrian Atmosphere

RECENTLY published age determinations<sup>1,2</sup> together with other figures<sup>3</sup> from British Guiana can be used to give more information about the Pre-Cambrian atmosphere. Ritten<sup>4</sup> has suggested that a tentative age of 1,000 million years for the oldest geological 'red beds' indicates a provisional minimum age for the present oxygenic atmosphere. He further suggests that the transition between the latter and an earlier anoxygenic atmosphere occurred between 2,000 and 1,000 m.y. ago. Older 'red beds' occur in British Guiana [and it is postulated here that the above transition was probably between 3,000 and 2,500 m.y. ago].

The Roraima Formation<sup>5,6</sup> consists of usually flat-lying sandstones and conglomerates with notable jasper horizons enabling a three-fold classification. The formation is several thousand feet thick and covers an area of approximately 175,000 square miles in British Guiana, Brazil and Venezuela with outliers in British Guiana (Berbice) and Surinam (Tafelberg). The sandstones are usually pink and the jaspers red or green. Approximately vertical cliffs several thousand feet high define the margins, forming the pink-coloured walls to flat-topped mesas, which are such a striking feature of the Roraima Formation (Mount Roraima is the setting of Conan Doyle's *Lost World*).

The Muruwa Formation<sup>7</sup> appears to underlie the Roraima Formation, forming a low-lying belt, approximately 20 miles wide, east-west across central British Guiana. Lithologically the rock-types are remarkably similar to the Roraima Formation, differing mainly in being folded about gently plunging fold-axes.

The pink colour of the sandstones of both formations and, in particular, the deeper red of the jaspers of the Roraima Formation and the cherty mudstones of the Muruwa Formation appear mainly due to haematite and limonite. Following Ritten<sup>4</sup>, and actualistic reasoning, these sediments were probably deposited under oxygenic conditions and, as shown below, appear to be the oldest types of these deposits (unequivocally dated) so far known.

Dolerites of the Younger Basic Intrusive Group form large sills intruding the Roraima Formation. McDougal, Compston and Hawkes<sup>8</sup>, from several determinations on pyroxenes and plagioclases from these dolerites, suggest an age of intrusion of just over 2,000 m.y. Snelling and McConnell<sup>9</sup> consider the latter age is probably too high, and from determinations on pyroxenes from similar dolerites, muscovite and biotite from the associated hornfelses, and a re-interpretation of the data of McDougal *et al.*, suggests the best estimate of the age of emplacement of the intrusives to be  $1,675 \pm 100$  m.y.

However, of immediate importance to the present note is that all the present data suggest a minimum age of the Roraima Formation of about 1,700 m.y.

In addition, the Roraima Formation unconformably overlies the Barama-Mazaruni Assemblage<sup>3</sup> and some of the granites of the Younger Granite Group. It has been suggested<sup>8</sup> that a post-Roraima granite may occur in Surinam, but the evidence is not conclusive. Minor acid dykes<sup>9</sup> intrude the Roraima but no post-Roraima intrusive granites have been mapped in British Guiana. Snelling<sup>3</sup> has dated several granites from the Younger Granite Group, the oldest within the northern eugeosyncline being the Kaituma Granite ( $2,065 \pm 100$  m.y.). In addition, the Kartabu Granite of the Bartica assemblage<sup>10</sup> has been dated at  $1,960 \pm 60$  m.y. A preliminary outline of the geology of British Guiana was recently published in *Nature*<sup>11</sup>.

Two granites intruding the Muruwa Formation have been dated<sup>3</sup> at  $1,570 \pm 50$  and  $1,760 \pm 55$  m.y., but Snelling (personal communication) has reservations about these dates. However, one granite intruding the Iwokrama Formation (which appears to overly conformably the Muruwa Formation) has been reliably dated<sup>3</sup> at  $2,595 \pm 125$  m.y.

It can be clearly stated, therefore, that the Roraima Formation is older than its intrusive dolerites and must be in excess of 1,700 m.y. Geological evidence strongly suggests that the Muruwa Formation is older; this is confirmed by the oldest granite noted above, which is approximately 2,600 m.y. and gives a minimum age to the Muruwa Formation of about 2,500 m.y.

A minimum age of 2,015 m.y. has been suggested<sup>3</sup> for the main phase of the post-Barama-Mazaruni-Bartica orogeny (the last major pre-Roraima orogeny), and this age is probably also the date of emplacement of many members of the Younger Granite Group. Any Pre-Cambrian tectonism modifying the ages of the rocks underlying the Roraima Formation must, of course, be limited by the flat-lying sedimentary deposits of the Roraima Formation, which are, therefore, probably younger than 2,000 m.y.—approximately 1,800–1,700 m.y. has been suggested<sup>3</sup> for their deposition.

A tentative age of 2,000 m.y. for the youngest sediments deposited under anoxygenic conditions has been suggested by Ritten<sup>4</sup>, though he notes that these deposits may range from 2,000 to 3,000 m.y. It seems likely from the above data that an oxygenic atmosphere was extant about 1,800 m.y. ago (Roraima Formation) and at least 2,500 m.y. ago (Muruwa Formation), and that any transition from a previous anoxygenic atmosphere occurred before 2,500 m.y., probably between 3,000 and 2,500 m.y. The overlapping of these ages with the suggested range (2,000 to 3,000 m.y.<sup>4</sup>) for the sediments deposited under an anoxygenic atmosphere clearly indicates that more data are required, particularly concerning the environment of the youngest sediments deposited under anoxygenic conditions (which may not, in all cases, reflect an anoxygenic atmosphere).

The above age determinations of British Guiana rocks (except for those in McDougal *et al.*<sup>1</sup>) were made by Dr. N. J. Snelling<sup>2</sup> at the Age Determination Unit, Overseas Geological Surveys in the Department of Geology and Mineralogy, University of Oxford.

### A Modified Staining Technique for Carbonates in Thin Section

POTASSIUM ferricyanide and alizarin red *S* are frequently used as stains for distinguishing between carbonate minerals. Potassium ferricyanide in acid solution produces Turnbull's blue with ferrous iron and it used to be thought that dolomite could be distinguished from calcite on the basis that dolomite alone contained ferrous iron. Recently this has been shown to be incorrect<sup>1</sup>, and it is now known that any carbonate mineral containing small quantities of ferrous iron will stain with potassium ferricyanide providing the carbonate can be made to react with an acid medium. Recent work<sup>2,3</sup> shows that alizarin red *S* in solution is probably the best method of distinguishing between the common carbonates.

Boiling, 30 per cent sodium hydroxide solution, as used by Freidman<sup>2</sup> for staining blocks and chips, has been found unsuitable for staining thin sections, as the mounting medium (Lakeside 70, Canada balsam) tends to dissolve. A weak hydrochloric acid solution does not attack the mounting medium. I have obtained satisfactory results with the procedure described here. A concentration of 3 per cent hydrochloric acid, or greater, at room temperature dissolves away the more soluble carbonates and hence is undesirable. At room temperature alizarin red *S* is most selective as a stain in a concentration of hydrochloric acid which falls between 1 per cent and 2 per cent. At the 1.5 per cent plus level the thickness of the thin section is greatly reduced and the staining becomes pale. At lower concentrations, the stain becomes so thick that it obscures the fine detail of the thin section. An important feature of the stain at the 1–2 per cent acid concentration is that with calcite a surface parallel to the *C*-axis is more deeply stained than one normal to that axis. This is important in fabric analysis where optic orientation patterns are required.

The potassium ferricyanide stain is successful over a range of acid concentrations, and as this solution is mixed with the alizarin red *S* solution the same acid concentration (1–2 per cent) is used. At room temperature, at these low concentrations, potassium ferricyanide does not react with siderite.

Distilled water must be used for making up all solutions and for washing off surplus stain from the thin sections after each stage of the procedure. Much more reliable results are obtained if the thin section to be stained is etched first (stage I of procedure). This pre-staining etch removes all grinding dust from the carbonate surface and is carried out for at least 10 and not more than 15 sec using 1.5 per cent hydrochloric acid. The etched section is then immersed in an acidified mixture of the two stains

(stage II). Each stain works independently, and there is no mutual interference. If the now partially stained section is immersed in an acidified solution of alizarin red *S* for a few seconds the colour differentiation of the carbonates is increased further, but it is important not to leave the section longer than 15 sec in the solution (stage III). After rapid but careful washing of the section in distilled water it is important to dry the stained surface as quickly as possible because the stain is relatively soluble in water. It is important not to touch the stained surface when drying as it is purely a surface precipitate and is easily rubbed off. To preserve and protect the now dried stain, during mounting or remounting, a layer of 'Durofix' is painted on to the surface with a soft camel-hair brush. The 'Durofix' is diluted with amyl acetate, in the ratio 'Durofix' : amyl acetate = 1 : 3, which readily evaporates, and when this layer is completely dry it has a refractive index very close to 1.54.

The details and consecutive stages of the procedure are shown in Table 1.

The distinction between dolomite and calcite, of which most ancient limestones are composed, is of considerable importance in limestone petrology. The modified staining technique described not only gives positive colour differentiation of these two important carbonate minerals but also, because of their different solubility in hydrochloric acid, gives a difference of thickness in thin section. Calcite is etched to approximately 15 $\mu$  thickness while dolomite remains at 30 $\mu$  thickness; this difference is readily observable with polarized light.

## METALLURGY

### Identification of a Beta-Tungsten Phase in Tungsten-Rhenium Alloys

PHASE diagram equilibrium studies in the binary tungsten-rhenium system show the presence of two phases over the range 0–65 wt. per cent rhenium at 1,500° C (ref. 1). A terminal solid solution having a body-centred cubic structure exists from 0 to about 27 wt. per cent rhenium, and a phase having a tetragonal sigma-type structure is found in the composition range 43–65 wt. per cent rhenium. In this investigation, alloys containing 13–45 wt. per cent rhenium prepared by vapour deposition

Table 1

Procedure		Time	Carbonate	Result
Stage I	Etching 1.5% HCl	10–15 sec	Calcite Ferroan calcite	Considerable etch
			Dolomite Ferroan dolomite	Negligible etch
Stage II	Staining* 0.2 g A.R.S. per 100 c.c. 1.5% HCl 2.0 g P.F. per 100 c.c. 1.5% HCl Mixed in ratio A.R.S. : P.F. = 3 : 2	30–45 sec	Calcite	Very pale pink—red depending on optical orientation
			Ferroan calcite	Very pale pink—red Pale blue—dark blue Two superimposed give Mauve—purple—royal blue
			Dolomite	No colour
			Ferroan dolomite	Pale—deep turquoise depending on ferrous content
Stage III	Staining 0.2 g A.R.S. per 100 c.c. 1.5% HCl	10–15 sec	Calcite Ferroan calcite	Very pale pink—red
			Dolomite Ferroan dolomite	No colour

\* A.R.S. = Alizarin red *S*. P.F. = Potassium ferricyanide

at 500°C were found to contain a phase having a  $\beta$ -tungsten type structure not previously reported in tungsten-rhenium alloys. The stability of this phase with respect to temperature and composition is now being examined. No evidence for the presence of sigma phase or elemental rhenium was found in these alloys as deposited.

The alloys were prepared by the simultaneous hydrogen reduction of tungsten and rhenium hexafluorides at 500°C, 10 torr total system pressure, and a mole ratio of reacting gases of  $H_2:WF_6:ReF_6 = 50:6:1$ . The deposit, which formed on the inner wall of a heated copper tube, was richer in rhenium near the inlet to the deposition zone than farther downstream. Thus, alloys ranging from 4 to 46 wt. per cent rhenium were available for examination.

X-ray diffraction patterns of powder samples were obtained using a 114-mm Debye-Scherrer camera with nickel-filtered copper radiation. The phases identified in several samples of different rhenium content and the visual intensity of lines on the diffraction patterns are shown in Table 1. A body-centred cubic  $\alpha$ -tungsten (A2) structure was the principal phase in the low-rhenium deposits. The lattice parameter of this phase approaches the value for unalloyed tungsten,  $a_0 = 3.1648 \text{ \AA}$ , with decreasing rhenium content. A previously unreported cubic  $\beta$ -tungsten structure (A15) was observed in the composition range 13–45 wt. per cent rhenium. Diffraction data for the  $\beta$ -tungsten structure measured from a pattern of a 22.3 wt. per cent rhenium sample are shown in Table 2. The lattice parameter of the  $\beta$ -tungsten structure was found to be  $a_0 = 5.0182 \pm 0.005 \text{ \AA}$  at this composition.

Hardness values and impurity concentrations of the deposits are presented in Table 3. The hardness values were obtained using a 500-g load on a Kentron hardness tester. The sharp drop in hardness with decreasing

rhenium content supports the X-ray evidence of solid solution or compound formation in the deposit. The impurity content, like hardness, decreases with decreasing rhenium content. Although impurity concentrations are rather high for the higher rhenium deposits, the generally excellent purity lends credibility to the interpretation of the X-ray diffraction data. In addition to the interstitial impurities shown in Table 3, copper, magnesium, and silicon were present in trace amounts.

Superconducting transition temperatures were observed at 6.4° and 8.8° K for samples containing 6 and 12 wt. per cent rhenium, respectively. As may be seen from Table 1, the major phase in these alloys was a solid solution of rhenium in the body-centred cubic lattice of tungsten. The  $\beta$ -tungsten structure was a minor constituent in both cases. R. D. Blaugher, A. Taylor and J. K. Halm measured  $T_c$  values of 2.4° and 4.6° K for alloys containing 15 and 25 wt. per cent rhenium, respectively<sup>2</sup>. These alloys were reported to be single phase.

We thank D. S. Easton for measuring the superconducting transition temperatures.

## CRYSTALLOGRAPHY

### Crystal-structure of Tetragonal Strontium Oxalate

Two aspects of the structure of tetragonal calcium oxalate (weddellite), namely: (1) that the oxalate ion has the symmetry  $mmm$ ; (2) that the crystalline salt has a water content of  $2 + \text{zeolitic } X \text{ H}_2\text{O}$  ( $X \leq 0.5$ ) (ref. 1), can be examined further. Klasens, Perdok and Terpstra<sup>2</sup> described tetragonal strontium oxalate as being isomorphic with weddellite, but they gave the number of molecules of water in the former as 2.5 and in the latter as 3.

Envelope crystals of tetragonal strontium oxalate were obtained by the method of the foregoing investigators<sup>2</sup>. After storage for several months in the laboratory, a small single crystal was subjected to a crystal-structure analysis. Data were obtained with copper- $K\alpha$  radiation, with intensities monitored by a scintillation counter. Because the largest dimension of the crystal was 0.1 mm, no absorption corrections were made.

The space group is  $I4/m$ , and the cell dimensions are  $a = 12.82 \pm 0.03$ ,  $c = 7.50 \pm 0.02 \text{ \AA}$ . The measured density of  $2.36 \text{ g cm}^{-3}$  (by flotation) gives slightly more than 8 formula weights of  $SrC_2O_4 \cdot 2H_2O$  per cell; specifically, the calculated water content is 2.17 moles of water per mole of strontium. The resolution of the structure followed readily from a 3-dimensional Patterson distribution, based on 607 independent reflexions. Refinement by least squares of a structure based on  $SrC_2O_4 \cdot 2H_2O$  proceeded until the discrepancy index,  $R$ , was 0.12. A difference Fourier synthesis showed the presence of a low electron-density peak on the 4-fold axis. Placement of the appropriate fraction (0.1) of a necessarily disordered water molecule at the indicated site, as with weddellite, permitted the refinement to continue somewhat further, lowering  $R$  to 0.11. The final atomic parameters are given in Table 1.

The crystal is thus completely isomorphic with that of weddellite, even having the same zeolitic water content

Table 1. ATOMIC PARAMETERS OF TETRAGONAL STRONTIUM OXALATE

Atom	<i>x</i>	<i>y</i>	<i>z</i>	B (Å <sup>2</sup> )
Sr	0.301	0.196	0.0	0.8
O(1)	0.469	0.231	0.179	3.5
O(2)	0.639	0.248	0.180	1.7
O(1 <sup>1</sup> )	0.106	0.149	0.0	4.8
O(2 <sup>1</sup> )	0.390	0.013	0.0	4.7
O(1 <sup>2</sup> )	0.0	0.0	0.282	4.3
O(2 <sup>2</sup> )	0.555	0.241	0.101	1.5

( $X \leq 0.5$ ). However, the unit cell of tetragonal strontium oxalate is slightly larger, and the average distance of Sr—O, for the 8-co-ordinated strontium atom, is 2.59 Å (2.56–2.61 Å).

The C—C bond of the oxalate ion is bisected by a symmetry plane. The bond-lengths are as follows: C—C,  $1.52 \pm 0.04$  Å; C—O(1),  $1.25 \pm 0.02$  Å, C—O(2),  $1.24 \pm 0.02$  Å. The bond angles are C—C—O(1),  $117.7 \pm 1.0^\circ$ ; C—C—O(2),  $118.5 \pm 1.0^\circ$ ; O(1)—C—O(2),  $123.8 \pm 1.7^\circ$ . The oxalate ion therefore has the symmetry *mmm*, within a very small limit of error.

## CHEMISTRY

### Octafluoroprotactinates (V)

ALTHOUGH potassium heptafluoroprotactinate (V),  $K_3PaF_7$ , has been known for several years<sup>1</sup> and a number of hexafluoroprotactinates (V),  $M_1PaF_6$ , ( $M_1 = NH_4^+$ ,  $K^+$  and  $Rb^+$ ) have been recently reported<sup>2</sup>, octafluoroprotactinates (V) have not been recorded. In an investigation of the preparation and properties of the fluoro-complexes of quinquivalent protactinium, using bromine trifluoride and aqueous hydrofluoric acid as solvents, we have isolated lithium and sodium octafluoroprotactinates (V),  $Li_3PaF_8$  and  $Na_3PaF_8$  respectively, from reactions in the latter solvent.

Solutions approximately 0.5 M in protactinium (V) were obtained by dissolving protactinium pentoxide,  $Pa_2O_5$ , previously ignited at  $750^\circ$ , in 48 per cent hydrofluoric acid. Sufficient alkali metal fluoride,  $MF$  ( $M = Li^+$ ,  $Na^+$  and  $K^+$ ), to give a 3:1 mole ratio of  $MF:Pa$  was dissolved in hydrofluoric acid, added to the protactinium (V) solution in a platinum crucible and the mixture concentrated to approximately half-volume by heating under an infra-red lamp. Addition of acetone to the mixtures containing sodium and potassium fluoride produced an immediate precipitate of octa- and heptafluoroprotactinate (V) respectively, the latter identified by its X-ray diffraction pattern<sup>3</sup>. Lithium octafluoroprotactinate (V), which was not formed under the afore-said conditions, could only be obtained by evaporating the hydrofluoric acid solution of the component fluorides to dryness and was identified from its X-ray powder pattern. The isolated products were vacuum dried at about  $100^\circ$ . Protactinium analyses were performed by dissolving the complex in 10 per cent nitric acid solution, precipitating the hydroxide and igniting it to the pentoxide at  $750^\circ$ . Fluoride in the supernatant was determined gravimetrically<sup>4</sup> as lead chloro-fluoride: found for the sodium complex: Pa, 49.38 per cent; F, 33.54 per cent; required for  $Na_3PaF_8$ : Pa, 51.1 per cent; F, 33.63 per cent.

The octafluoroprotactinates (V) are white, non-hygroscopic solids, which are soluble in dilute hydrofluoric acid, water and dilute nitric acid. It is interesting to note that no signs of hydrolysis are observed in the last two solutions, further evidence of the strong fluoride-complexing of protactinium (V). Both are immediately

hydrolysed by ammoniacal solution. The sodium salt is isostructural with<sup>5</sup> sodium octafluorouranate (V), possessing tetragonal symmetry. The lithium complex, for which there appears to be no quinquivalent niobium, tantalum and uranium analogue, is also tetragonal; owing to the presence of several weak reflexions, extra to those observed on the powder pattern of  $Na_3PaF_8$ , the X-ray powder diffraction data are best interpreted on the basis of a larger cell obtained by doubling  $a_0$ . The results of the diffraction investigations are shown in Table 1, the lithium and sodium salts having the space groups  $P4_22_12-D_2^5$  and  $I/mmm-D_{2h}^{17}$  respectively.

Table 1. UNIT CELL DATA

Compound	Symmetry	$a_0$ (Å)	$c_0$ (Å)	<i>n</i>	(g/cm <sup>3</sup> )
$Li_3PaF_8$	Tetragonal	10.386	10.89	8	4.568
$Na_3PaF_8$	Tetragonal	5.487	10.89	2	4.577

We understand from Dr. A. G. Maddock<sup>6</sup> that he and his associates, working at Cambridge, have also recently prepared  $Na_3PaF_8$  using conditions similar to those for the preparation of the tantalum (V) analogue. Our preliminary report of the preparation of the octafluoroprotactinates (V) will be supplemented by a detailed account of their chemistry, to be published elsewhere, including a full structure analysis of  $Na_3PaF_8$  and of potassium heptafluoroprotactinate (V) and the isostructural sodium and rubidium complexes.

### Compounds containing Mercury—Iron Bonds

Hock and Stuhlman<sup>1</sup> discovered that the reaction of iron pentacarbonyl with mercuric halides yielded solid products, which they formulated as addition compounds  $Fe(CO)_4Hg(HgX_2)_2$ , containing the  $Fe(CO)_4Hg$  moiety which itself can be obtained by reaction of iron pentacarbonyl and mercuric sulphate. No structural information on these compounds is available, although Wells<sup>2</sup> has suggested that  $Fe(CO)_4Hg$  is polymeric and *trans*.

We find that although the compounds  $Fe(CO)_4Hg_2X_2$  are sufficiently soluble in polar solvents to permit recrystallization, they do not give sufficiently concentrated solutions for mol. wt. or dipole moment determination. Their elemental analyses and infra-red spectra ( $2,200$ – $175$   $cm^{-1}$ ) can be consistently explained on the basis of a monomeric structure, *cis*- $Fe(CO)_4(HgX)_2$ , in which there are two mercury-iron bonds.  $Fe(CO)_4Hg$  is insoluble in all organic solvents and is most probably polymeric; both it and the corresponding cadmium compound we also believe to have the *cis*-configuration with mercury or cadmium-iron bonds.

The pattern of carbonyl stretching frequencies is typical of that found for *cis*- $M(CO)_4L_2$  molecules. For *trans*- $M(CO)_4L_2$  only one band would be expected. The spectra of all five compounds (Table 1) are similar in the region  $620$ – $400$   $cm^{-1}$ , where  $\delta(MCO)$  and  $\nu(M-CO)$  modes absorb<sup>3</sup>, and contain more bands than would be expected for a *trans*-structure. A further, very weak, feature near  $250$   $cm^{-1}$  is common to all spectra and may be the first overtone of a  $\delta(CFeC)$  mode. The only other band in the  $Fe(CO)_4Hg$  spectrum,  $195.9$   $cm^{-1}$  (s), we assign to a mercury-iron stretching mode on the grounds that no vibrational mode of an  $M(CO)_n$  grouping is likely to absorb in that region<sup>3</sup>. Consistent with this assignment is the

† Broad band with three unresolved components: approximate frequency only.

presence of bands at 216 and 226 cm<sup>-1</sup> (ν(Cd-Fe)), in Fe(CO)<sub>4</sub>Cd, which has an equally simple spectrum. For comparison, in Hg[Co(CO)<sub>4</sub>]<sub>2</sub> and Cd[Co(CO)<sub>4</sub>]<sub>2</sub>, ν(M-CO)(sym.) is at 152 and 161 cm<sup>-1</sup> respectively<sup>4</sup>, while ν(Pt-Sn) and ν(Rh-Sn) are found<sup>5</sup> near 210 cm<sup>-1</sup>. In the compounds cis-Fe(CO)<sub>4</sub>(HgX)<sub>2</sub>, for X = Cl, Br, there are no bands in the regions in which HgX<sub>2</sub> absorbs<sup>6</sup>, disproving the original suggestion that these are addition compounds.

Vibrations of the Hg-X and Hg-Fe bonds must interact substantially, particularly for the bromide and iodide, so that it is not reasonable to make assignments to ν(Hg-Fe) or ν(Hg-X): they must be regarded as normal modes of the Fe(HgX)<sub>2</sub> framework. For X = Cl, although there must be interaction, it may be reasonable to assign the 292 and 272.6 cm<sup>-1</sup> bands to modes involving mainly Hg-Cl stretching. In that event, absorption at 219 cm<sup>-1</sup> is assigned to ν(Hg-Fe). ν(Hg-Cl) in Fe(CO)<sub>4</sub>(HgCl)<sub>2</sub> is comparable with that<sup>6</sup> in Hg<sub>2</sub>Cl<sub>2</sub> and may be taken to indicate that mercury is in oxidation state I (ref. 7).

We have also investigated the reaction of mercuric chloride with the complexes Fe(CO)<sub>5-n</sub>(PPh<sub>3</sub>)<sub>n</sub> (n = 1, 2, 3) (ref. 8). These do not add two Hg-Cl groups. A typical product is Fe(CO)<sub>2</sub>(HgCl)Cl(PPh<sub>3</sub>)<sub>2</sub>, from n = 2, analogous to that of mercuric chloride on IrCl(CO)(PPh<sub>3</sub>)<sub>2</sub> (ref. 9).

## Optical Resolution of a DL-Amino-acid by a Stereoselective Ligand Exchange Reaction

Few investigations of the utilization of metal chelate compounds for the optical resolution of racemic compounds have so far been reported<sup>1-4</sup>. DL-Aspartic acid copper complex was optically resolved completely from its super-saturated solution by seeding it with D- or L-aspartic acid copper complexes<sup>1</sup>. Bailar *et al.* first reported the stereo-specific (stereoselective) ligand exchange reaction<sup>2</sup>, and

later they reported the partial optical resolution of DL-alanine by use of the reaction of DL-alanine with copper glutamate (optical purity 3.3 per cent<sup>3</sup>). Recently, Shibata *et al.*<sup>4</sup> reported the partial optical resolution of DL-alanine in 25.6 per cent optical purity by use of the aspartic acid cobalt(III) complex.

In this communication the optical resolution of DL-aspartic acid by the use of stereoselective ligand exchange reactions is described. Copper complexes of D- and L-alanine, D- and L-glutamic acid, and L-proline were used in this reaction. This simple procedure for the optical resolution of DL-aspartic acid resulted in 95-100 per cent optically active D- and L-aspartic acids.

Typical examples are as follows: L-alanine, 1.78 g (0.02 mole), was heated at 80° C with 6.0 g of copper carbonate in 50 ml. of water for 10 min. Unreacted copper carbonate was removed by filtration. To the L-alanine copper complex solution, DL-aspartic acid, 2.66 g (0.02 mole) in 100 ml. of water was added and the solution was filtered. The solution was allowed to stand for 30 h. The precipitated crystals were filtered and washed with cold water and ethanol. A yield of 1.27 g of D-aspartic acid copper complex was obtained. The copper complex was dissolved in 30 ml. of 2 N hydrochloric acid and was treated with hydrogen sulphide. Copper sulphide was removed by filtration and the solution was treated with charcoal. After filtration, the solution was concentrated to dryness. The dried D-aspartic acid hydrochloride was dissolved in 5 ml. of water and the pH was adjusted to 2.8-3.0 with pyridine. D-Aspartic acid crystallized. The addition of 10 ml. of alcohol resulted in 0.54 g of free D-aspartic acid. The aspartic acid was free of alanine as determined by paper chromatography and on the automatic amino-acid analyser; [α]<sub>D</sub><sup>25</sup> = -23.3, in 6 N hydrochloric acid, C = 1.27; anal. calc. for C<sub>4</sub>H<sub>7</sub>NO<sub>4</sub>: C, 36.09; H, 5.30; N, 10.52; found: C, 35.91; H, 5.41; N, 10.30.

In the same way, D-alanine copper complex (0.02 mole) was treated with DL-aspartic acid (0.02 mole). After standing for 30 h, 1.39 g of L-aspartic acid copper complex was obtained. From this, 0.54 g of free L-aspartic acid was isolated, [α]<sub>D</sub><sup>25</sup> = +23.0°, in 6 N hydrochloric acid, C = 1.36; anal. found: N, 10.48.

Similar reactions were carried out in the combination of (L-glutamic acid copper complex and DL-aspartic acid), (D-glutamic acid copper complex and DL-aspartic acid) and (L-proline copper complex and DL-aspartic acid). Results are shown in Table 1.

Table 1

Amino-acid to compose copper complex	Amino-acid to be resolved	Resolved aspartic acid* Yield (g)	Configu- ration	[α] <sub>D</sub> <sup>25</sup> ~ <sup>26</sup>	% Optical purity
L-Alanine (0.02 mole)	DL-Aspartic acid (0.02 mole)	0.54	D	-23.3	95
D-Alanine (0.02 mole)	DL-Aspartic acid (0.02 mole)	0.54	L	+23.0	93
L-Glutamic acid (0.02 mole)	DL-Aspartic acid (0.03 mole)	1.07	D	-24.7	100
L-Glutamic acid (0.025 mole)	DL-Aspartic acid (0.025 mole)	0.85	D	-24.2	98
L-Glutamic acid (0.03 mole)	DL-Aspartic acid (0.02 mole)	1.10	D	-15.6	63
D-Glutamic acid (0.02 mole)	DL-Aspartic acid (0.03 mole)	0.85	L	+24.7	100
L-Proline (0.02 mole)	DL-Aspartic acid (0.03 mole)	0.59	D	+24.1	98

\* Resolved aspartic acids were chromatographically pure. Elemental analysis of these resolved aspartic acids agreed with the theoretical value. Specific rotation of pure L-aspartic acid: [α]<sub>D</sub><sup>25</sup> = +24.72° in 6 N hydrochloric acid, C = 8.00.

The mechanism of the reaction has not yet been clarified. However, it is likely that the configuration of the entering amino-acid in the ligand exchange reaction is a mirror image structure of the amino-acid which composes the copper complex. Fig. 1 shows the possible mechanism of this reaction in which two L-amino-acids approach the copper complex composed of the two D-amino-acids.

Fig. 1

The stereoselective reaction is not only interesting as a new method of optical resolution of  $\alpha$ -amino-acids, but is also interesting as an explanation of the development of optical activity of amino-acids in pre-biological systems<sup>5</sup>. Once an optically active amino-acid arose (for example by the spontaneous resolution of glutamic acid from aqueous solution<sup>6</sup>), the optical activity might be transferred to other amino-acids successively through various metal chelate compounds.

### Line-width Alternation in the Electron Spin Resonance Spectra of *Para*-dinitrobenzene Anions in Various Mixed Solvents

As part of a general investigation of ion-solvent and ion-ion interactions by spectrometric methods we have monitored the changes in the electron spin resonance spectrum of the anion of *para*-dinitrobenzene in methanol on addition of a variety of solvents. The isotropic hyperfine coupling to <sup>14</sup>N in the two nitro-groups ( $a_{AV}^N$ ), which is particularly sensitive to changes in solvent, is plotted against the mole-fraction of added solvent in Fig. 1. It was observed, however, that of the five components associated with <sup>14</sup>N, those having  $m_N = \pm 1$  ( $m_N$  being the *Z* component of the nitrogen nuclear spin angular momentum), namely the second and fourth sets of lines, were often much broader than the remaining lines. Results are given in Fig. 2 and a typical spectrum is shown in Fig. 3a.

This phenomenon is comparable with that reported by Fraenkel *et al.* for the anions of the dinitrodurenes<sup>1</sup> and dinitromesitylenes<sup>2</sup> and for the *meta*-dinitrobenzene anion<sup>3</sup>; but these workers found no linewidth alternation for the *ortho*- or *para*-isomers in dimethyl formamide<sup>3,4</sup> even at  $-50^\circ\text{C}$ . Indeed, that for the *meta*-isomer was only barely detectable at room temperature.

Because of its marked instability the anion of *para*-dinitrobenzene was prepared by *in situ* ultra-violet

photolysis of methanolic solutions of *para*-dinitrobenzene containing 0.2–0.3 M sodium methoxide. We were unable to examine solutions containing less than about 30 per cent mole-fraction of methanol as secondary products, mainly the *para*-nitroanisole anion, obscured the spectra before they could be accurately monitored.

Fig. 1. Variation of  $a_{AV}^N$  for the anion of *para*-dinitrobenzene in methanol with added solvents: A, methylene chloride; B, *t*-butanol; C, diethyl ether; D, tetrahydrofuran; E, methyl cyanide; F, acetone; G, dimethoxyethane.

Fig. 2. Variation of line-width parameter *P* for the anion of *para*-dinitrobenzene in methanol with added solvents; same key as Fig. 1.

Fig. 3. *a*, A typical spectrum of the sodium salt of the *para*-dinitrobenzene anion showing line-width alternation; *b*, theoretical reconstruction showing the effect of fluctuation in the nitrogen hyperfine coupling constants  $a_1^N$  and  $a_2^N$  about the mean value  $a_{AV}^N$

$$a_1^N + a_2^N = a_{AV}^N = \text{constant}$$

$$|a_2^N - a_1^N| = 2\delta$$

In order to allow for the effect of anisotropic hyperfine interactions and  $g$ -values on the line-widths, the results in Fig. 1 have been recorded as a plot of the mean amplitude of the lines corresponding to  $m_N = 0, \pm 2$  to that of the lines corresponding to  $m_N = \pm 1$ . The value of this ratio for two equivalent  $^{14}\text{N}$  nuclei, showing a 1:2:3:2:1 intensity distribution, should be 0.83. Amplitudes of the derivative lines have been used since this is by far the most sensitive parameter to slight changes in width.

Fraenkel *et al.* have suggested that the alternation found by them for the *meta*-isomer at low temperatures stems from an asymmetric solvation which, either directly by altering spin-densities, or indirectly by encouraging an out-of-plane twist by one nitro-group, causes a fluctuation in the nitrogen hyperfine coupling constants about the mean value  $a_{AV}^N$ .

The way this affects the line-widths is depicted in Fig. 3*b*. The distance of lines 1 and 5 from the centre of the spectrum is equal to  $(a_1^N + a_2^N)$ , which is a constant, while the distance of lines 2 and 4 from the centre fluctuates between  $a_1^N$  and  $a_2^N$ . The central line will be composed of a narrow component of unit intensity superimposed on a broadened component of twice this intensity.

Our results demonstrate that unsymmetrical solvation is not the cause of this alternation for the *para*-isomer. Thus, for example, on adding methyl cyanide there is a steady decrease in  $a_{AV}^N$ , but no change in  $P$  is detectable, whereas methylene chloride causes a marked change in  $P$  but scarcely changes  $a_{AV}^N$ .

In our view the two nitro groups are likely to experience an almost equivalent solvation at all times except when in the vicinity of a cation. Thus we assign the alternation

to asymmetric ion-pair formation, the cation staying preferentially close to one or other of the nitro groups. If the ions were in direct contact then we would expect  $a_{AV}^N$  to be modified and to be a function of the size of the cation. The fact that in many instances  $a_{AV}^N$  scarcely changes at all suggests that the ions are present as solvent-separated ion-pairs<sup>5</sup> and that in solvent mixtures containing either methylene chloride, *t*-butanol or diethyl ether, the anion still comes into direct contact with methanol molecules. The marked effect of dimethoxyethane on  $a_{AV}^N$  then stems from the fact that this solvent solvates the cations, thus displacing methanol from the region between the ions.

The strong shift caused by methyl cyanide and acetone is reminiscent of the effect of these solvents on the ultra-violet spectrum of solvated halide ions<sup>6</sup> and may stem from the same cause. Thus methanol probably solvates very intimately by bonding to the oxygens of the nitro-groups, whereas methyl cyanide is expected to solvate more generally and hence more loosely, thus causing less disturbance of the spin density distribution in the anion.

### Effect of Water Vapour on the Sensitivity of a Macro-argon Ionization Detector

As part of a comprehensive investigation into the physics of various forms of ionization detector for use in gas chromatography, it became necessary to determine the effect of water vapour on detector sensitivity. Lovelock<sup>1</sup> shows a graph which indicates that the sensitivity of a macro-argon detector was reduced 10-fold by a change in water vapour concentration from about 30 p.p.m. to about 1,000 p.p.m. v/v. At less than 30 p.p.m. of water vapour, the detector response is constant<sup>2</sup>.

A steady stream of 500 ml./min of ordinary commercial argon from the British Oxygen Co. was passed through a drying train consisting of two U-tubes filled with Linde type 13 x molecular sieve, in series with a further two U-tubes filled with phosphorus pentoxide. The water content of the issuing gas was certainly less than 1.5 p.p.m. v/v. The all-metal apparatus was continuously purged with this dry gas unless an experiment was in progress. The dry gas was then passed into a sulphuric acid saturator which produced known concentrations of water vapour<sup>3</sup>. This wet gas was fed into a power-driven syringe dilution system. The syringe was loaded with saturated diethyl ether vapour as the test substance. After injection of the ether vapour into the argon stream, the gas was passed into a metal ballast chamber, and thence into a flow splitter. 100 ml./min was fed into the macro-argon detector (Lovelock<sup>4</sup>) which was thermostatted at 50° C. On emerging from the detector, the stream passed into an electrolytic hygrometer<sup>5</sup>, in order to measure the water vapour concentration. The ionization current signal from the Pye macro-argon detector was measured with an Ekco vibrating reed electrometer type N616A, and displayed on a Honeywell potentiometric recorder. The detector was polarized with a stabilized voltage of 800 V derived from a type 532/D extra high tension power unit by Isotope Developments, Ltd.

Fig. 1 shows the response of the detector to various levels of ether vapour when dry argon was used. It confirms, in a general fashion, the results of Wiseman, quoted by Littlewood<sup>6</sup>. To obtain the results shown in Fig. 2, a constant test concentration of 5.8 p.p.m. v/v of diethyl ether vapour was used, and the concentration of water vapour varied in the argon supply. The concentration of test substance is of the same order as that of Desty, Geach and Goldup<sup>7</sup>, who used 2.6 p.p.m. of *n*-heptane in their evaluation of a flame ionization detector. It is seen that even a change in concentration of water vapour from 8 to 10 p.p.m. reduces the response of the detector to 5.8 p.p.m. of ether vapour by some 20

Fig. 1. Plot of ionization current against concentration of di-ethyl ether in a macro-argon detector, using dry argon

Fig. 2. The effect of various concentrations of water vapour in the argon carrier gas on the sensitivity of a macro-argon detector to a constant level of 5.8 p.p.m. of diethyl ether vapour

per cent. Hence it is clear that, for quantitative work, an effective drying train must be placed in the argon feed line to the detector, and the whole system thoroughly dried out as recommended by Evans and Scott<sup>2</sup>. The reduction in sensitivity is probably due to the attachment of electrons to water molecules to form negative ions having a lower mobility, Wilkinson<sup>8</sup>. Measurements were also made of the water vapour concentration in argon obtained straight from the cylinder, and Table 1 shows the results for several cylinders selected at random. With a cylinder having a pressure of 1,000 lb./in.<sup>2</sup> or more, the water concentration is likely to be of the order 3 p.p.m. This low level confirms the unpublished work of Hill in 1962 that the sensitivity of a micro-argon detector (Lovelock<sup>4</sup>) was not increased by placing a cold trap at -78° C in the argon line.

Cylinder No.	Cylinder pressure (lb./in. <sup>2</sup> )	Measured humidity (p.p.m. v/v)
1	1,350	2.5
2	880	1.5
3	850	6.0
4	90	10.9
4	50	15.9
4	27	35.4
5	22	4.5

Constant argon flow rate from cylinders of 500 c.c./min.

Even though dry argon is used, it may well be possible for the injection of a series of wet samples on to a column which holds back water vapour to give rise to a steady eluted concentration of water vapour which is sufficient to affect the detector sensitivity.

W. G. Pye, Ltd., kindly lent the detector to us, and the Hirst Research Centre of the General Electric Co. gave advice on the operation of the electrolytic hygrometer. This work was supported by the Sir Halley Stewart Trust.

## BIOCHEMISTRY

## Deoxyribonucleic Acid Content of Basal Cells of Mouse Epidermis

STUDIES on mouse-ear and body-skin epidermis have led Gelfant<sup>1,2</sup> to the conclusion that there are two distinct populations of epidermal cells, one with a  $G_2$  period of a few hours, the other with a  $G_2$  period as long as five days. Bullough<sup>3</sup> has commented on the work of Gelfant and stated that his results are statistically inadequate. In view of the general uniformity in length of the  $G_2$  period in mammalian cells studied so far<sup>4</sup> of approximately 2–4 h, the existence of a population of cells with an unusually long  $G_2$  period is of some importance. It seemed worth while, therefore, to determine the distribution of DNA levels in epidermal cells, using a densitometric method, since a pronounced peak would be found at the tetraploid level if a sizeable population of cells were in the  $G_2$  state.

Pieces of skin were removed from the ears and backs of hairless mice immediately after they were killed by cervical fracture. Care had been taken not to stress the animals during the previous week<sup>5</sup>. The skins were left for 24 h at 2° C in a solution of 0.5 per cent acetic acid. At the end of this time the epidermis was peeled off the underlying connective tissue and soaked in acetic/methanol (1:3) for 30 min. The basal cells were then gently scraped off the keratin layer on to glass coverslips, squashed in a press, air-dried, and stained by the Feulgen method<sup>6</sup>, using

pararosaniline dye (Chroma). A Barr and Stroud integrating microdensitometer was used to measure the absorption of the cells at 5500 Å. Leucocytes from a mouse were smeared on the coverslips prior to staining in order to establish the diploid DNA-level. This level did not alter if leucocytes were initially exposed to acetic acid in the same way as the skin.

Histograms are shown of the DNA-levels of the basal cells of the thin epidermis of the ear in Fig. 1 (100 cells), and the multilayered epidermis of the dorsal skin in Fig. 2 (50 cells). The cells in both cases were almost entirely diploid. Scanning several hundred other cells by eye failed to reveal more than an occasional cell with a tetraploid amount of DNA. Similar distributions of DNA-levels were found in basal cells obtained from the skin of hirsute (random bred Hall Institute) mice. Since there is normally a slow turnover of basal cells<sup>7,8</sup>, it is to be expected that some cells would be in the  $G_2$  phase. However, no evidence was found of a large population in this phase. Hypodiploid nuclei were evident and could be obtained in quantity by more vigorous scraping of the keratin layer. A reduction in the DNA content of epidermal cells undergoing keratinization has been reported<sup>9</sup>.

## Progressive Hyperglycaemia in Experimental Obesity of Albino Rats

THE coincidence of two hereditary metabolic disorders, diabetes and obesity<sup>1,2</sup>, is quite common although their interrelationship is still a matter of speculation as there is no proof that obesity causes diabetes. On the other hand, the importance of various physiological conditions, such as obesity, puberty or pregnancy, in precipitating diabetes cannot be overlooked. Few experimental observations record their coincidence. Mayer *et al.*<sup>3</sup> showed the connexion between obesity and diabetes in an obese-hyperglycaemic strain of mice. Long<sup>4</sup> mentioned that only with great difficulty was a temporary diabetes-like state induced in hypothalamic obesity in albino rats by partial pancreatectomy. Except for the observation of Katsuki *et al.*<sup>5</sup>, who induced obesity and hyperglycaemia by gold thioglucose injection in intact mice, there is no recorded evidence that in intact animals hyperglycaemia results from obesity. While investigating the metabolic character of obese albino rats, we had already noticed that the fasting blood sugar was significantly high in these animals in comparison to control animals<sup>6</sup>.

An investigation into the carbohydrate metabolism of obese albino rats, in which obesity was induced and maintained for a longer period, was therefore undertaken to detect any correlation between obesity and hyperglycaemia.

Thirty-six male albino rats of this Institute's colony were divided between two equal groups and maintained on a standard stock diet and a 40 per cent fat diet, respectively. Both groups were treated with 'P.Z.' insulin as recorded earlier<sup>6</sup>. Glucose tolerance tests were performed periodically on the surviving rats of the control and obese groups at 7, 10 and 12 months. At 10 months, when the fasting blood glucose-level was high, blood

inorganic phosphate was also estimated by the method of Taussky and Shorr<sup>7</sup>. Simultaneously with the glucose tolerance test, pyruvic and lactic acids in blood collected from tail vein were also estimated by the methods of Friedman and Haugen<sup>8</sup> and of Barker and Summerson<sup>9</sup>, 0, 1.5 and 3 h after glucose (Table 1). Each estimation was repeated at least twice.

Progressive increases in the fasting blood sugar-levels were noticed (Table 2) at 7, 10 and 12 months in both the groups. The values ranged from 85–106, 147–153 and 160–188 mg per cent in control, and 103–146, 145–182 and 167–222 mg per cent in the obese group at 7, 10 and 12 months, respectively. Except at 12 months, the fasting blood sugar in the obese group was significantly higher than that in control.

The peak value (1 h after glucose) in the obese group was always significantly higher than that in the control group, the ranges being 138–149, 158–199 and 169–203 mg per cent in the control, and 137–192, 173–238 and 197–238 mg per cent in the obese group at 7, 10 and 12 months, respectively. There was no significant difference in blood glucose values in the two groups afterwards. The fasting blood level of inorganic phosphate, which was significantly higher in the obese group (Table 2), came down to a significantly lower level compared to normal group 1 and 2 h after glucose. Three hours after glucose the blood level of pyruvic acid was identical in both the groups (0.5 mg per cent). Its fasting level was significantly lower in the obese group (Table 1). The fasting level of lactic acid, which was significantly higher in the obese group (13.2 mg per cent) compared to control group (7.5 mg per cent), recorded progressive significant increase to 23.5 and 29.7 mg per cent compared to control values of 14.6 and 13.6 mg per cent at 1.5 and 3 h, respectively.

The resistance of intact rats to the hyperglycaemic episode is well known. It is practically impossible to induce persistent hyperglycaemia and diabetes in intact animals of this species by means other than surgical or chemical pancreatectomy. It was reported by Ingle<sup>10</sup> that when insulin formation was suppressed in albino rats by the prolonged injection of insulin, its subsequent withdrawal led to a diabetes-like state. In the present work,

impairment of glucose tolerance or hyperglycaemia could not be explained on the foregoing basis as both groups of animals were treated similarly.

Prolonged feeding of a high fat diet causes lowering of glucose tolerance in man. Haist<sup>11</sup> reported that high fat diet caused reduction of the insulin content of  $\beta$  cells. Both the foregoing observations indicate partial functional failure of insulin apparatus on prolonged fat feeding. However, it is difficult to come to such a conclusion on the basis of our observation, particularly as changes in blood inorganic phosphate level (Table 2) strongly indicate a normal phosphorylation mechanism which is under the direct control of insulin and must always precede glycolysis.

Fig. 1

The obese rat has accumulated a disproportionate mass of body fat (above 30 per cent, Fig. 1). The high metabolic activity of fat tissue in the mobilization of endogenous fat and oxidation of glucose has been unquestionably established<sup>12</sup>. That a very rapid mobilization of body fat at this site might impede glucose oxidation in muscle was conceived by Randle<sup>13</sup>. Unmistakable evidence of failure of the oxidative process to keep up with the glycolytic reaction after glucose administration is demonstrated by the rise in pyruvic acid in both groups, and by the mounting lactic acid level in the blood of the obese rats, which is significantly higher than the controls. It can be imagined that the hyperglycaemia recorded here may be due to rapid mobilization of fat resulting in the accumulation of breakdown products which might block the oxidative processes through which the products of glycolysis must pass for the complete oxidation of glucose. The importance of the present observation lies in the fact that here progressive hyperglycaemia has been a direct consequence of the induction of obesity in intact normal rats.

This material was presented, in my absence, to the Fifth Congress of the International Diabetes Federation, Toronto, July 1964.

## Determination of the N-terminal Amino-acid in Polypeptides and Proteins

THE weakest point in the DNP-method<sup>1</sup> is the destruction of the N-terminal DNP-amino-acid which occurs under the conditions of hydrolysis necessary to detach it from the protein. The optimum time of hydrolysis for an end-group analysis is the time at which DNP-peptides are no longer present; this is different with every protein, but overnight hydrolysis (16–24 h) with constant boiling HCl is routine. The extent of destruction is different with each protein, and is generally much greater than would be expected for any free DNP-amino-acid under the same conditions of hydrolysis in the absence of protein. It is not possible to correct for destruction by hydrolysis for a graded series of times and extrapolation to zero time, for much of the destruction seems to take place during the initial hours of the hydrolysis before degradation has proceeded to small fragments. Thus, although the DNP-method has been, and will doubtless continue to be, widely used for end-group analysis, it is slowly being superseded by stepwise degradation methods.

With reference to this, in a preliminary investigation we have centred our attention on halogeno-di-nitropyridines and halogeno-nitropyrimidines. Among the several reagents proposed, 2-Cl-3,5-di-nitropyridine and 2-Cl-5-nitropyrimidine are the most interesting; they react under mild conditions (pH 8.5, room temperature) to give derivatives which are very soluble in organic solvents<sup>2,3</sup>.

Evidence in the literature<sup>4</sup> suggests that internal attack by the nitrogen atom at the carbonyl carbon would facilitate the cleavage of the first peptide bond. The object of this communication is to present a new technique for the determination of the N-terminal amino-acid in peptides and proteins by means of 2-Cl-3,5-dinitropyridine:

During the course of our investigations on some dinitropyridyl-peptides (DNPyr-peptides) we have observed a noteworthy acid and basic catalysis on the cleavage of peptide bond. The following derivatives: DNPyr-Ala-Gly, DNPyr-Gly-Gly, DNPyr-Leu-Leu, DNPyr-Ala-Phe and DNPyr-Pro-Gly in HCl 6 N at 60° C or in HCOOH 90 per cent at 100° C for 2 h<sup>5</sup>, release quantitatively Gly, Gly, Leu, Phe and Gly in that order (Table 1). In these conditions the recovery of any terminal dinitropyridyl-amino-acid (DNPyr-amino-acid) is almost quantitative; on the contrary, the DNPyr-amino-acids show different stability in boiling HCl, 6 N, with a maximum of decomposition for DNPyr-Ser, DNPyr-Thr and DNPyr-Pro. Good results were obtained by performing the hydrolysis in HCl, 6 N, at 60° C with formic acid; the use of formic acid is necessary as it is a solvent for many proteins.

Table 1. RELATIVE RATE OF HYDROLYSIS OF DNPYR-PEPTIDES

Compound	Recovery of terminal DNPyr-amino-acid*	T <sub>1/2</sub>	
		(HCl 6 N 60° C)	(HCOOH 90% 100° C)
DNPyr-Ala-Gly	95	5'	5'
DNPyr-Ala-Phe	96	31'	32'
DNPyr-Gly-Gly	98	51'	48'
DNPyr-Leu-Leu	95	45'	46'
DNPyr-Pro-Gly	92	40'	42'

\* These values are corrected only for chromatographic losses.

As shown in Table 1, the rate of hydrolysis of peptide bonds of different stability (Leu-Leu or Gly-Gly) is quite similar.

For the determination of the N-terminal amino-acid in a polypeptide chain the procedure is as follows: about 1 μM of protein and an equal weight of NaHCO<sub>3</sub> are dissolved or suspended in 1 ml. of water in a 25 ml. round-bottomed flask or test-tube of convenient size. To this is added twice the volume of an ethanolic solution of 2-Cl-3,5-dinitropyridine and the mixture is shaken for 2 h at room temperature. It is then acidified with a few drops of concentrated HCl diluted with 5 ml. of water and shaken with several 5 ml. portions of ethyl acetate, decanting after each extraction; this removes ethanol, excess 2-Cl-3,5-dinitropyridine and 2-OH-3,5-dinitropyridine, and leaves an aqueous suspension of the insoluble DNPyr-protein.

The hydrolysing acid (HCl 6 N with 30 per cent formic acid) is then added and hydrolysis is effected for 8–10 h at 60° C. The reaction mixture is transferred to a test-tube, diluted with water and extracted with four 5-ml. portions of ethyl acetate; the combined ethyl acetate extracts are then washed with small portions of water to remove ε-DNPyr-lysine peptides, the washings being returned to the aqueous phase. After evaporation of the ethyl acetate extracts the residue is quantitatively transferred to the paper chromatogram with small portions of acetone: the best two-dimensional system is that of Levy<sup>6</sup>. The end-group spot is then cut out and dropped into a 2 × 15 cm test-tube: 1 per cent sodium bicarbonate is added and the tube placed in a water bath at 60° C for 30 min. The optical density at 340 mμ (360 mμ in the case of DNPyr-Pro) is read in a Beckman model DU spectrophotometer against an extract of blank paper<sup>7</sup>.

The application of our method to known proteins has confirmed its validity so far as the quantitative determinations of glycine and phenylalanine in insulin and of lysine in lysozyme are concerned.

This method has three particular advantages: (a) the condensation with the terminal amino group is quantitative and relatively free from side reactions; (b) the DNPy-amino-acids produced are bright yellow, which is very helpful for their micromanipulation, chromatography and photometric estimation; (c) the terminal DNPy-amino-acids are quantitatively recovered after hydrolysis of the polypeptide chain.

### Breakdown of Caffeine in the Leaves of *Coffea arabica* L.

THE caffeine content of older *Coffea* leaves decreases after an initial increase in young leaves<sup>1</sup>. There are two possible explanations of this fact; first, a chemical transformation of caffeine; secondly, a translocation from the leaf to other organs. The object of these investigations was to find out if there is a breakdown of caffeine in the *Coffea* leaves and what compounds are formed. Four differently labelled caffeine molecules were synthesized, two with <sup>14</sup>C in the purine ring (pos. 2 and 8) and two with <sup>14</sup>C in the methyl groups (N1-methyl <sup>14</sup>C and N7-methyl <sup>14</sup>C).

To determine whether there is a caffeine breakdown in the leaves, a radioactive caffeine solution was fed through the petiole to isolated *Coffea* leaves (feeding time 8 h). After 10 days the leaves were dried and pulverized, and the total radioactivity of the dry powder was determined. Part of the dry powder was extracted and the extract was chromatographed (Whatman No. 1, *n*-butanol / NH<sub>3</sub> (*d*: 0.91) / H<sub>2</sub>O, 86:5:14). The total activity of caffeine was determined. In older leaves there was a large difference between the total activity of dry powder and the total activity of caffeine still present. This difference is accounted for by the breakdown products of the preceding 10 days of incubation. My experiments showed that the breakdown rate of endogenous and of fed caffeine was almost the same.

Single leaves were fed in a plastic chamber through which air was sucked. After passing through the chamber the CO<sub>2</sub> was absorbed by a KOH solution. The older leaves released measurable amounts of radioactive CO<sub>2</sub> when they were fed with ring-labelled as well as with methyl-labelled caffeine. These experiments showed that a complete breakdown of the caffeine molecule in the metabolism of the leaf is possible.

To determine the different breakdown products, *Coffea* leaves, still connected with the tree, were fed with radioactive caffeine through the mid-rib (feeding time 1-2 days). Ten days later the leaves were gathered, frozen with liquid air, pulverized and extracted with 80 per cent ethanol. The concentrated extract was co-chromatographed with expected breakdown products (2-dim., Whatman No. 1; butanol / acetic acid / water (4:1:1); ethanol / acetic acid / water (81:5:14). X-ray papers were pressed on the chromatograms and exposed for 2 months. The developed co-chromatographed compounds

on the paper chromatograms and the radioactive spots on the X-ray papers were compared. The radiograms of C2- and C8-labelled caffeine did not show essential difference in the arrangement of spots. The feeding experiments with N1-methyl <sup>14</sup>C-caffeine showed the same arrangement of radioactive compounds as the experiments with N7-methyl <sup>14</sup>C-caffeine. The position of radioactive compounds on the radiograms is shown in Fig. 1. Three unknown substances, X, Y and Z, appeared not only in experiments with ring-labelled but also with methyl-labelled caffeine.

Fig. 1. Summary of the radiograms of the caffeine breakdown products. BAW, ethanol / acetic acid / water (81:5:14); BAW, butanol / acetic acid / water (4:1:1); all, allantoin; ala, allantoic acid; u, urea; mx, methyl-xanthine; X, Y and Z, unknown substances; ca, caffeine

In order to identify the breakdown products of caffeine I performed several groups of experiments. In the first group I investigated whether *Coffea* leaves degrade caffeine to methylated xanthines and uric acids, as do some mammals. No radioactivity was detectable in the different mono- and dimethyl uric acids. A radioactive spot coincided with 3- or/and 7-methyl-xanthine. In the second group of investigations allantoin, allantoic acid and urea were co-chromatographed with extracts of C2- and C8-feeding experiments. In both experiments the production of large amounts of radioactive allantoin and smaller amounts of active allantoic acid and urea could be demonstrated. The extracts in feeding experiments with methyl-labelled caffeine showed no activity in different amino-acids connected with Cl-metabolism (serine, citrulline, arginine, methionine).

After feeding experiments with C2- and C8-labelled caffeine the radioactivity was localized in the allantoin molecule. Alkaline and acidic hydrolysis degraded allantoin first to allantoic acid and to urea plus glyoxylic acid. After these hydrolyses the extract was chromatographed and the chromatogram autoradiographed. The whole activity of allantoin was recovered in urea. The identity of this urea was proved in a parallel trial by degradation with the enzyme urease. This experiment demonstrated that only the C-atoms of the ureido-groups of allantoin were radioactive. This fact indicated that allantoin is a real breakdown product of caffeine.

The experiments showed the path of carbon 2 and 8 of caffeine. There are a number of unknown intermediates between caffeine and allantoin. Allantoin is the precursor of allantoic acid and urea. The release of <sup>14</sup>CO<sub>2</sub> by the

leaves makes it probable that radioactive urea is hydrolysed by urease in the leaves of the *Coffea* tree. A more detailed report of these experiments will be published later<sup>2</sup>.

### Solubilization of Keratins by Reaction with Ethylene Oxide

THE reactions of keratins and other proteins with epoxides have been described by several investigators<sup>1</sup>. The chemical modification of wool by reaction with mono- or di-functional epoxides in aqueous or alcoholic solution at or near room temperature has also been studied. In general, the acid and alkali solubility is decreased by reaction with di-functional epoxides, but increased if a monofunctional epoxide is employed<sup>2</sup>. We have recently found, however, that quite different results are obtained if wool is heated with ethylene oxide and a small amount of *N,N*-dimethylaniline with no solvent, as described by Haas *et al.*<sup>3</sup> for making hydroxy-ethyl nylon. Under these conditions, the wool fibres are disintegrated and the product is soluble in water. Part of the ethylene oxide does not react and part is converted to polyethylene glycol which can be extracted from the aqueous solution with methylene chloride or toluene, although the latter solvent forms troublesome emulsions which are much more persistent than those formed by methylene chloride. A very small part of the ethylene oxide apparently becomes attached to the solubilized wool.

As an example, 0.960 g wool cloth was sealed in a glass tube with 10 ml. ethylene oxide and 0.1 g *N,N*-dimethylaniline in a nitrogen atmosphere (no special precautions were taken to include or exclude moisture) and heated at 80° C for 25 h. The viscous, syrupy reaction product was washed out of the tube with water, and the resulting aqueous solution was exhaustively extracted in a continuous extractor with methylene chloride. The syrupy extract weighed 6.2 g. The aqueous phase was clarified by centrifuging; the residue in the centrifuge tube, on drying, gave a solid that weighed 2.9 mg. The weight of the water-soluble, methylene chloride-insoluble fraction, estimated by drying an aliquot to constant weight, was 1.724 g. John J. Bartulovich, of this laboratory, found by ultracentrifugation (in a preliminary determination by the Archibald method) that the material not extracted from the aqueous solution by methylene chloride had a weight average molecular weight of about 10,000. Wilfred H. Ward, also of this laboratory, found that the material passed through a dialysis membrane, which indicated that the molecular weight cannot greatly exceed 10,000. The precise extent of degradation of the protein thus remain to be determined.

Other fibrous proteins solubilized by this procedure are: mohair, ovokeratin, cattle horn, and silk fibroin. In one trial with fibroin, complete solubilization was obtained, but in others only one-fifth or one-fourth of the silk was solubilized. The insoluble silk remaining after the reaction with ethylene oxide and *N,N*-dimethylaniline retained the fibrous appearance and structure.

When wool that has received a polyamide treatment applied by the interfacial polymerization procedure<sup>4</sup> is used, the wool is solubilized and the polyamide sheath is undissolved.

Work is in progress on the nature of the water-soluble reaction product resulting from the reaction of ethylene

oxide with the protein, and the procedure may be useful in fundamental keratin studies.

### Estimation of Urinary Oxalate by the Method of Isotope Dilution

DURING the course of a series of metabolic experiments in which 1-<sup>13</sup>C-ascorbic acid and 1-<sup>13</sup>C-glycine were fed to a normal adult<sup>1</sup> and hyperoxaluric patients<sup>2</sup> daily samples of urinary oxalic acid were isolated as calcium oxalate for estimation of the <sup>13</sup>C enrichment. It was found expedient to determine the daily levels of excretion by the method of isotope dilution, using the specific <sup>14</sup>C-activity of the oxalate samples prior to combustion to CO<sub>2</sub> for mass spectrometric analysis. The amounts of <sup>14</sup>C and <sup>13</sup>C added were low and hence did not interfere with the measurement of <sup>13</sup>CO<sub>2</sub>. Previously reported methods for calcium oxalate estimation have the disadvantage that they depend on the complete recovery of oxalate from a sample of the urine<sup>3-7</sup>. Using the method of isotope dilution, however, the only exacting requirement is the purity of the final product, which is checked by repeated reprecipitation to constant specific activity.

Twenty-four-hour urine collections were made in 40 ml. of 6 N HCl, and after the addition of 1 : 2-<sup>14</sup>C-oxalic acid (1 µc., 0.2 µg) sufficient concentrated HCl was added to bring the concentration to 2 N and the whole was continuously extracted for 16 h with peroxide-free ether. The ether phase was evaporated in the presence of water (5 ml.) and the aqueous residue was treated with 0.880 NH<sub>4</sub>OH (1–2 ml.). Saturated CaCl<sub>2</sub> (0.5 ml.) was added and the precipitated (COO)<sub>2</sub>Ca.H<sub>2</sub>O was purified by solution in 2 N HCl (5–7 ml.), decolorization with 'Norit' and precipitation with 0.880 NH<sub>4</sub>OH and acetic acid at pH 5.2 (brom-cresol purple). Samples were counted by the liquid scintillation technique (Nuclear Chicago Instrument, model 725) using 100-µl. aliquots (taken from the HCl solution prior to re-precipitation) and a dioxan-based phosphor (10 ml. 'Panax', type T.E.D.). At the concentration used (0.1–0.5 mg of (COO)<sub>2</sub>Ca.H<sub>2</sub>O) no quenching due to calcium oxalate was observed, and the counting efficiency was 51 per cent. The disintegrations per min were calculated from an efficiency curve established by adding different volumes (25–300 µl.) of 2 N HCl to a known radioactive standard (Packard, Standard Source Toluene <sup>14</sup>C) in 10 ml. of phosphor and applying the 'Channels Ratio' method<sup>8</sup>. The purification process was repeated until the specific activity remained constant (usually three re-precipitations were adequate). In some cases the purity of the final product was also checked by dissolving 1–2 mg in 2 N H<sub>2</sub>SO<sub>4</sub> (5 ml.) and determining the oxalic acid by the method of Hodgkinson and Zarembski<sup>4</sup>. In any isotope dilution analysis the total amount of substance present is inversely proportional to its specific activity and the amount of urinary calcium oxalate was calculated from its specific activity, compared with that of a standard prepared from the same 1 : 2-<sup>14</sup>C-oxalic acid.

During metabolic experiments lasting 19 and 15 consecutive days<sup>2</sup>, a normal adult gave daily (COOH)<sub>2</sub>.2H<sub>2</sub>O excretions of 41.8 mg. (S.D. ± 4.6 mg) and 26.7 mg (S.D. ± 4.6 mg) respectively, whereas a hyperoxaluric

child studied for 28 consecutive days gave  $82.1 \text{ mg}$  ( $S.D. \pm 23 \text{ mg}$ ) per day. Values obtained for 3 consecutive days on the same hyperoxaluric child by the method of Archer *et al.*<sup>3</sup> were  $63.9 \pm 4.8$ ;  $40.0 \pm 2.5$  and  $37.7 \pm 2.4$ , while the isotope dilution method applied to the same urine samples gave values of  $80.8 \pm 2.8$ ;  $72.4 \pm 0.8$  and  $58.1 \pm 0.6$  respectively, expressed as  $\text{mg}$  of  $(\text{COOH})_2 \cdot 2\text{H}_2\text{O}$  per 24 h. Although it is possible that oxalogenic compounds in urine may produce as much as 10 per cent of the total oxalate during the acid-ether extraction period<sup>4</sup>, we suggest that the higher values obtained by isotope dilution are largely a reflexion of the sensitivity of the method.

We thank Prof. E. F. Scowen and Dr. R. W. E. Watts for their help and advice.

### Disruption of Mast Cells by a Component of Eosinophil Granules

EOSINOPHILS are phagocytic cells, and granules adjacent to the phagocytic vacuole rupture<sup>1</sup>. Eosinophil granules contain a number of acid hydrolases together with basic protein and peroxidase<sup>2</sup> and during phagocytosis these substances are discharged from the disrupted granules into, or alongside, the phagocytic vacuole. The acid hydrolases released from eosinophil granules probably have a digestive function, but the significance of the other granule components is not known. This work reports the presence in eosinophil granules of a substance capable of causing the disruption of mast cells. The active principle appears to be associated with the enzyme peroxidase.

Eosinophils were obtained from rats of the Long Evans strain, using the methods previously described of peritoneal lavage and centrifugation of peritoneal cells in albumin<sup>3</sup>. Contaminating red cells present in the eosinophil cell button were lysed by the addition of 2 ml. of a 0.2 per cent sodium chloride solution. The cells were suspended in the hypotonic saline solution for 15 sec. after which time the tube was filled with physiological saline and centrifuged. Eosinophils constituted approximately 90 per cent of the cells present, the remainder being mononuclear cells. Basic protein and peroxidase were extracted into solution from the eosinophil granules by the addition to intact cells of 2 ml. 0.05 M acetate buffer at pH 3.7. The supernatant solution obtained after centrifugation was added to 10 ml. 0.2 per cent ammonium hydroxide solution and a precipitate was formed.

The precipitate was redissolved in 0.05 acetate buffer at pH 4.5 to a concentration of approximately 10 mg protein/ml. and applied to a 'Pevikon' block. 'Pevikon powder' C870 (Stockholms Superfosfat Fabriks Aktiebolag, Stockholm) was mixed with a small volume of 0.05 acetate buffer at pH 4.5 and moulded into a block, 12 in.  $\times$  4 in.  $\times$  0.5 in., for electrophoresis. Electrophoresis was performed for 8 h at 250 V and 10 m.amp. when the block was cut into sections 0.5 in. in width, and

Fig. 1. (A) The appearance of 6 normal rat mast cells by phase contrast microscopy. (B) Same cells following introduction of an isotonic solution containing the peroxidase rich eluate at pH 7. Granules have escaped from the swollen cells.

eluates were obtained. Protein estimations on the eluates were performed by the method of Lowry *et al.*<sup>4</sup> and peroxidase was estimated by the guaiacol method of Chance and Maehly<sup>5</sup>. The activity of the peroxidase present was recorded in protein equivalents of crystalline horse-radish peroxidase. Crystalline horse-radish peroxidase, batch 62602A, was obtained from Nutritional Biochemical Corporation, New Jersey. Fresh mast cells were obtained from the peritoneal cavity of rats and were not separated from other peritoneal cells<sup>6</sup>. One drop of mast cells suspended in physiological saline was added to a mixture consisting of one drop of eluate, one drop of 0.2 sodium phosphate buffer at pH 7, and three drops of saline. Those eluates found to cause mast cell disruption were diluted in saline to the limit at which disruption of added mast cells occurred. The eluate containing the maximum amount of peroxidase was concentrated by ultrafiltration and re-applied to a 'Pevikon' block. Electrophoresis was repeated on a 'Pevikon' block at pH 5.8 in 0.05 M phosphate buffer. The peroxidase-rich fraction obtained after the second electrophoresis was submitted again to electrophoresis at pH 5.8. Eosinophil peroxidase has an absorption band in the Soret region maximal at 415 m $\mu$  (to be published) and the various preparations of peroxidase were tested for absorption at 415 m $\mu$  and 280 m $\mu$  using a Zeiss model P.M.Q. absorptiometer.

Results are shown in Table 1 of the estimations of protein and peroxidase concentrations in the eluates obtained from the 'Pevikon' block.

Table 1

Distance from origin towards cathode (in.)	Protein concentration in eluate ( $\mu\text{g}/\text{ml.}$ )	Peroxidase concentration in eluate ( $\mu\text{g}/\text{ml.}$ )	Disruption of added mast cells
0.0	0	0	0
0.5	0	0	0
1.0	0	0	0
1.5	0	0	0
2.0	5	0	0
2.5	155	28	0
3.0	94	36	0
3.5	16	50	+
4.0	90	108	+++

Maximum protein concentration was found in the eluate obtained 2.5 in. from the origin towards the cathode and maximum peroxidase concentration was found 4 in. from the origin. Mast cell disrupting activity was found in the eluate 4 in. from the origin (see Fig. 1) and weak activity against mast cells was found in the eluate at 3.5 in., the ratio of the absorption at 415 m $\mu$  to that at 280 m $\mu$ , for the various peroxidase preparations, was as follows:

Acid extract of eosinophils before electrophoresis	0.06
Peroxidase-rich fraction after first electrophoresis	0.45
Peroxidase-rich fraction after second electrophoresis	0.72
Peroxidase-rich fraction after third electrophoresis	0.80

Disruption of mast cells occurred when eluates obtained from each electrophoresis procedure were added to mast cells. The minimum protein concentration which caused mast cell disruption in these eluates was approximately  $1 \times 10^{-5}$  mg/ml. It is not known whether the substance causing disruption of mast cells is peroxidase but the absorption ratio of the fraction obtained after the third electrophoresis compares closely with the 430/280 ratio of 0.82 obtained by Agner for crystalline myeloperoxidase<sup>7</sup>.

It is known that eosinophils are attracted to sites of antigen-antibody reaction<sup>8</sup>, and granule lysis occurs during phagocytosis by eosinophils of antigen-antibody complexes. Liberation of granule components from the cells to the surrounding tissues has not been shown to occur but it seems probable. The component of the eosinophil granule active against mast cells may then be released to the surrounding tissues, causing disruption of local mast cells.

We thank Mr. Nikolai Kalcenaus for technical assistance.

## PHYSIOLOGY

### Interpretation of Skin Impedance Measurements

HUMAN skin presents a high impedance to alternating current of low frequency<sup>1</sup>. The impedance is greatly reduced if the surface layers of the skin are abraded<sup>2</sup>. When the frequency of the applied a.c. is raised above 10 c/s, the impedance falls; the equivalent circuit is a polarization impedance in parallel with a resistance<sup>3</sup>. The impedance of rabbit or pig skin is less than that of human skin, and is also less dependent on frequency (Fig. 1).

Fig. 1. Impedance of skin in contact with 0.9 per cent sodium chloride as a function of frequency of applied alternating current

I have investigated how the impedance to low-frequency a.c. recorded from skin is influenced by the way in which contact is made with the skin surface. A circular metal plate (0.2–14 cm<sup>2</sup>) was pressed down at 100 g/cm<sup>2</sup> on the dry-shaved dorsal surface of a man's forearm in a cool environment, and the impedance between this plate and a 15-cm<sup>2</sup> silver plate moistened with Cambridge electrode jelly on the volar surface was measured by a bridge technique, using 1.5-c/s a.c. at 1 V root mean square. Higher voltage produced non-linearity in response. Immediately on contact between the metal and the skin the impedance was very high ( $\gg 10$  M $\Omega$ ); it fell rapidly to reach a nearly steady value ( $Z$ ) within 10 min of contact. This steady value was inversely related to the area ( $A$ ) of the metal plate; the best fit was given by  $Z = kA^{-1.28}$ . As the divergence from inverse proportionality was small, results were expressed in impedance  $\times$  area, specific impedance (Table 1). Silver, aluminium and iron plates all gave the same specific impedance on the same skin region, and so did mercury, confined in a 1.5 cm<sup>2</sup> 'Perspex' ring. Powdered gold applied between a metal plate and the skin did not affect the impedance, nor did variation of the contact pressure in the range 30–300 g/cm<sup>2</sup>. Obstruction of the hair follicles with silicone grease before applying the metal plate raised the impedance slightly ( $Z_1/Z_0 = 1.32$ , 5 per cent fiducial limit 0.94–1.70 in 9 experiments), but placing similar grease spots between the hairs also raised the impedance slightly ( $Z_1/Z_0 = 1.18$ , 5 per cent fiducial limit 0.99–1.29).

Table 1. SPECIFIC IMPEDANCE OF SKIN TO 1.5-C/S A.C.: MEAN AND 5 PER CENT FIDUCIAL LIMITS

Species	Skin contact	Impedance (k $\Omega$ cm <sup>2</sup> )
Man, forearm	Silver	6,800 (5,200–8,400; 22 expts.)
	Agar gel	480 (150–810; 6 expts.)
	Saline	880 (590–1,170; 9 expts.)
Pig, flank	Saline	12 (8–16; 11 expts.)
Rabbit, flank	Saline	18 (11–26; 9 expts.)

With damp electrodes quite different results were obtained. Similar experiments to the aforementioned were performed, except that the dry-metal contact was replaced by 0.9 per cent sodium chloride in agar gel (area 0.16–3.5 cm<sup>2</sup>) to which electrical connexion was made both by voltage-recording and current-carrying silver wires. The impedance recorded was much less than with the dry electrode (Table 1), and fell only slightly with time of contact; after 5 min it was constant. The specific impedance (impedance  $\times$  area) was least for the smallest area; over the whole area range it varied by a factor of 1.8.

0.9 per cent sodium chloride solution, confined in a 4-cm<sup>2</sup> silastomer ring on the skin, gave a rather higher impedance than the agar gel; the difference was not significant (Table 1). A similar experimental arrangement on the clipped flank skin of an anaesthetized rabbit or pig showed a much lower impedance (Table 1).

The reciprocal of specific impedance, the specific admittance, is the current flow per unit E.M.F. and area. If the skin is adequately hydrated and the a.c. applied is of sufficiently low frequency, this should theoretically be proportional to the skin permeability to the current-carrying ions within the stratum corneum. The admittances of human, pig and rabbit skin under 0.9 per cent sodium chloride are in the ratio 1:73:49, while their permeabilities to Na<sup>+</sup> ions are in the ratio 1:27:42 (ref. 4). Thus both the animal skins are more permeable to ions and more conductive than human skin.

When the skin surface is not deliberately hydrated, the admittance should be a measure of the hydration of its surface layers provided that the contact between the electrode and the outermost cells of the stratum corneum is adequate. Since addition of contacting materials (gold dust, mercury) or increase of pressure does not increase the current flow, this is probably so. The small effect of greasing the hair follicles indicates that most of the current flows through the exposed epidermis in human skin.

The high specific impedance observed with small dry electrodes, and the low specific impedance observed with small wet electrodes, could both be due to lateral movement of water within the stratum corneum, in the first case drying the area under the electrode and in the second dampening the surrounding area.

These results indicate the conditions under which electrical impedance through skin can be interpreted in terms of the physical parameters of the stratum corneum.

### Retinal Ganglion Cell Activity in Cats during Dark Adaptation

THE existence in complete darkness of a tonic retinal discharge is well known<sup>1-3</sup>. There still exist, however, some questions as to its origin and functional significance.

In an attempt to investigate the possible origin of the tonic dark discharge we have measured as a function of time the firing rate of single retinal ganglion cells [ $r(t)$ ] from the moment of light cut-off until the retina returns to the condition of dark adaptation. By correlation of this activity with the classical light threshold changes during dark adaptation some conclusion may be drawn as to the effect of receptor activity on tonic dark discharge.

Results reported here are based on measurements of approximately 100 retinal cells from approximately 50 cats. Each cat was pre-trigeminally sectioned<sup>4</sup>, injected with curare to prevent movement, and placed under artificial respiration. Rectal temperature and blood pressure were monitored during the experiments. The eye was opened (cornea and lens removed) and 5–10  $\mu$  steel microelectrodes placed in the retina. Most probably, all recordings were from large ganglion cells<sup>4</sup>. The entire retina was illuminated from a light source approximately 20 cm from the eye. Only those recordings were used in which a single cell's activity could be easily distinguished on the basis of amplitude. Amplified pulses were fed to a Beckman 7360 counter and observations made of the firing rate as a function of time. To measure light threshold changes (no attempt was made to measure absolute threshold) we applied bursts of light every 30–60 sec. The bursts were synchronized with the pulse counter to facilitate detection of small rate changes and lasted 300 msec. Threshold was taken to be the smallest value of light-burst intensity which produced a noticeable change in firing rate.

The general procedure was as follows: (1) light threshold and average firing rate were measured for the dark-adapted eye; (2) strong light (4,000 lux) was applied for some minutes; (3) firing rate and threshold were recorded, beginning from the moment of light cut-off.

Our results may be divided into two parts, concerning respectively the transient  $r(t)$  immediately following the onset of darkness, and the long-time (tonic) rate variations. Transient responses of on-cells differed markedly from those of off-cells, while long-time dark discharge behaviour did not significantly differ between the two types of cell.

The figure shows a typical result for transient behaviour. In the off-cell the transient after darkness has two prominent features: (a) a short (5–10 sec) large initial burst of activity; (b) a second, longer-lasting hump beginning after approximately 20 sec. In the on-cell the transient following darkness is an abrupt drop in rate followed by an exponential increase to a steady state rate  $R_0$ . The form is approximately  $r(t) = R_0 (1 - \exp - t/\tau)$ . In

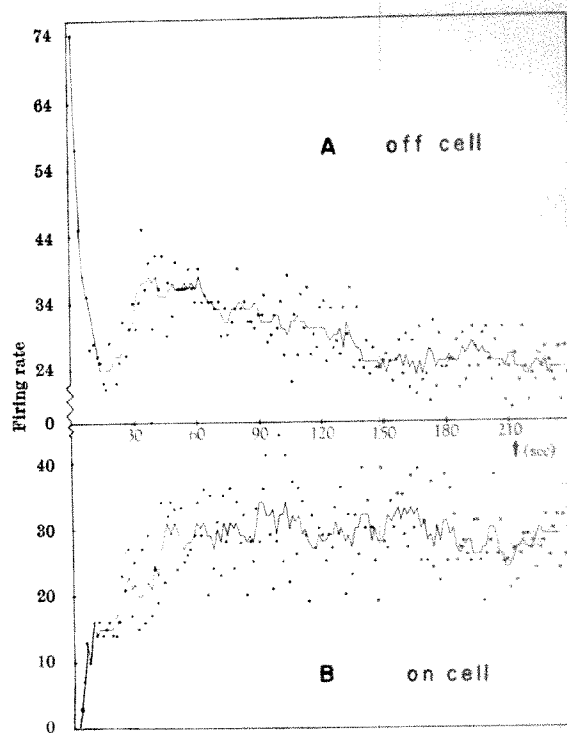

Fig. 1. Typical ganglion cell firing rate transients  $r(t)$  in discharge per sec plotted against time. For both examples strong retinal illumination of more than 5 min was turned off at  $t=0$ . The points represent actual readings every two seconds. The solid curve (except for the first several points) represents a short-time average (over 10 sec) calculated as a visual aid. The firing rate of the off cell (A) during the preceding illumination was 0 discharges per sec, while that of the on cell (B) was 48 discharges per sec. Note that the off cell plot ordinate does not begin at zero.

the example shown in Fig. 1,  $R_0$  is approximately 30 discharges per sec and the time constant  $\tau$  is approximately 30 sec.

Long-time rate changes after the onset of darkness were measured for as long as unit firing was countable. This was usually 30–45 min, sometimes 60–80 min, and in two or three cases for up to 2 h. In summary, we observed no systematic trends. After the initial transient the cell average firing rate remained relatively constant for a very long time.

The measurements of light threshold changes during dark adaptation revealed two salient features: (1) The threshold to light burst was almost always a monotonically decreasing function of time. The time it took for the threshold to become sensibly constant was in agreement with classical results (approx. 30 min) and always was at least 10 times as long as the duration of the firing rate transient. For this purpose the duration of the firing rate transient was defined as the time necessary for the firing rate to return to a condition indistinguishable from that prior to light exposure. (2) There was never any observable correlation between variations in light threshold and variations in firing rate after the transient period. We made no measurements of threshold during the transient period.

Summing up, the time-course of threshold changes tested by means of short pulses of light and the time-course of the spontaneous firing rate of the same ganglion cell are completely different. From this observation, some conclusions can be drawn. First, any process of dark adaptation, either limited to the receptors<sup>6</sup> or involving the neural elements of the retina<sup>7,8</sup>, does not influence the ganglion cell dark discharge, at least after the transient period. Secondly, the dark discharge is likely to represent the spontaneous activity of de-afferented retinal neurones. Thirdly, since there is good evidence that the visual threshold during the process of

dark adaptation is determined neurally rather than at the receptor level<sup>7,8</sup>, it is likely that the dark deafferentation occurs between the bipolar and the ganglion cell.

This research was sponsored jointly by the Office of Scientific Research, OAR, through the European Office, Aerospace Research, United States Air Force, under grant AF-EOAR 63-9, and by the Rockefeller Foundation.

### Intracellular Action Potentials associated with the Beating of the Cilia in Ctenophore Comb Plate Cells

IN ctenophores the tall columnar cells which bear the large cilia are about  $100\mu \times 8-12\mu$ , arranged in groups along the combs<sup>1</sup>. The large size of the cells makes it possible to record intracellular potentials which occur at each beat of the cilia. Although there is a good deal of previous work on the relations between membrane potential and ciliary activity in Protozoa<sup>2</sup>, no accounts of intracellular potentials from metazoan ciliated cells have come to hand.

Pieces of comb plate are cut from specimens of the Venus's girdle, *Cestus veneris*, about 50 cm long, and firmly held down in a wax dish by means of fine cactus spines. Usually the cilia then beat slowly at regular intervals and can also be aroused to give a single beat by a very gentle tap to the bench. Under direct observation a KCl-filled glass microelectrode (which must be 30-100 M ohms to be successful) is lowered into the cushion of ciliated cells just at the region of the ciliary basal bodies. Negative-going extracellular potentials, in the form of small peaks of a few millivolts and about 0.1 sec duration, are recorded before the electrode enters a cell. They vary greatly in height as the electrode presses to different extents against the cell. Resting potentials up to 40 mV are recorded as the electrode enters; at the same time the action potentials reverse in sign and now have a long falling phase (Fig. 1). The maximum height of action potentials was 27 mV at 15° C. The action potential is similar whether the beat is spontaneous or set off by a minute vibration. At this first attempt technical difficulties prevented successful recording of the mechanical movement and it is not possible to say whether the electri-

cal change starts before or after the beat of the cilia. The beat is, however, terminated in 0.2-0.4 sec and the potential change lasts much longer. Action potentials are graded, the smaller ones corresponding with weaker beats and larger ones with stronger beats. When two beats occur in quick succession the action potential of the second stands on the first as in Fig. 1b, although the two mechanical beats are quite separate. All cells have similar responses. No pacemaker or generator potentials have been seen. Depolarization of the cell by damage with the electrode causes the cilia of that cell, and of neighbouring cells, to beat rapidly. This can lead to a continual quivering of a small group of cilia. Although it is impossible to identify individual cells from which recordings are made in these circumstances, the quivering of cilia is found when the resting potential declines away to nothing. These small movements are not propagated.

This is the tissue for which the term "neuroid transmission" was first coined<sup>3</sup>, meaning propagation from cell to cell, but the results reported here fail to elucidate the mechanism by which the groups of ciliated cells are co-ordinated among themselves or between groups. It seems reasonable to conclude that the depolarization of the cell sets off the beat of the cilia of that cell. The ciliated cells lie close against each other, and their closely apposed membranes in some places closely resemble electrical synapses without vesicles<sup>4</sup>, as do some muscle fibre contacts in ctenophores. The beat of the ciliated cells is inhibited by a nerve net which spreads over the whole ectodermal surface and the ciliated cells have synapses on them only at their basal ends, far from the cilia<sup>4</sup>, showing that the whole cell must be electrically active for them to be effective. Post-synaptic potentials are presumably so attenuated that they are not observable in records from the ciliated ends of the cells.

This work was carried out at the Stazione Zoologica, Naples, and I thank the director, Dr. P. Dohrn, for the facilities which made it possible. Among his staff, I particularly thank Dr. R. A. Chapman, whose apparatus was used for the intracellular recordings.

### Metabolic Effect of Epinephrine on the $Q_{O_2}$ of the Arrested Isolated Perfused Rat Heart

SYMPATHETIC amines increase the oxygen consumption of the myocardium and it has usually been assumed that this is related primarily, if not exclusively, to the increase effected in rate and contractility. The present investigation demonstrates an increase in myocardial oxygen consumption due to epinephrine during potassium-induced cardiac arrest, that is, in the absence of any chronotropic or inotropic effect. This metabolic increase in oxygen consumption is accompanied by an increase in glycerol release into the perfusion medium, suggesting that the rate of utilization of endogenous lipids rises.

Fed male albino rats were decapitated, and their hearts removed and perfused following the method of Morgan *et al.*<sup>1</sup>. 15-30 c.c. of modified Krebs' bicarbonate buffer<sup>2</sup> was used, equilibrated with 95 per cent  $O_2$  and 5 per cent  $CO_2$ .  $Q_{O_2}$  was calculated from arterio-venous  $pO_2$  differences, measured with a Clark  $O_2$  macroelectrode, and from the  $O_2$  solubility constant, flow rates being measured directly. Perfusions were carried out at 37.5° C.

In the first series of experiments, using beating hearts (Series A, Table 1),  $Q_{O_2}$  was measured at 20 min in 11

Fig. 1. Intracellular records from ciliated comb plate cells. a, At each beat there is a positive-going action potential with a rapid rising phase and a slow falling phase; b, at 5 times the recording speed, three beats, artificially initiated by small vibrations, follow each other rapidly, forming a staircase; c, the graded nature of the action potentials is shown by a small spontaneous potential, which was accompanied by a weak beat of the cilia.

Table 1. EFFECT OF EPINEPHRINE IN BEATING AND ARRESTED PERFUSED RAT HEARTS

Conditions	$Q_0$ (ml. $O_2$ /min/g dry wt)	No.	Glycerol release ( $\mu$ g/g dry wt/h)	No.

Epinephrine	$0.92 \pm 0.03^*$ ( $P < 0.005$ )	11	$290 \pm 35^*$ ( $P < 0.01$ )	6
Arrested hearts (Series B)				
Control period	$0.28 \pm 0.02^*$	8		
After addition of epinephrine	$0.41 \pm 0.02^*$ ( $P < 0.005$ )†			

\* Standard error of the mean (S.E.M.).

† Calculated from S.E.M. of differences between paired values from single hearts (mean difference  $0.14 \pm 0.02$ ).

control hearts and in 12 hearts perfused from zero time with medium containing epinephrine,  $0.1 \mu\text{g/ml}$ . Some of these perfusates were then analysed to determine free fatty acids (FFA) and glycerol release. In a second set of experiments (Series B, Table 1), the hearts were arrested by using a perfusate containing  $31.3 \text{ mM K}^+$  (reducing the concentration of  $\text{Na}^+$  to maintain isotonicity).  $Q_0$  was measured at 15 min, by which time a stable baseline control  $Q_0$  had been reached. Epinephrine was then added to the perfusate ( $0.1 \mu\text{g/ml}$ ) and  $Q_0$  was measured again in the same preparation after 15 min. FFA were measured by Dole's titration method<sup>3</sup>. Glycerol was determined enzymatically<sup>4</sup>.

As shown in Table 1, there was a significant epinephrine stimulation of  $Q_0$ , of 58 per cent over control values in the beating heart (Series A). This was accompanied by a significant increase in glycerol release. There was no demonstrable release of FFA.

The hearts arrested with potassium (Series B) showed a lower control  $Q_0$ , presumably due to the lack of contractile activity. It should be noted that whereas  $10\text{--}12 \text{ mM K}^+$  caused arrest in the absence of epinephrine, a potassium concentration of  $31.3 \text{ mM}$  was necessary to maintain the hearts in arrest in the presence of epinephrine. The same concentration of potassium was used in the control period. Epinephrine produced a highly significant (46 per cent) stimulation of  $Q_0$ .

Though epinephrine caused a comparable percentage elevation of  $Q_0$ , of approximately 50 per cent in both the beating and the arrested hearts, the absolute value of the increment in arrested hearts ( $0.13 \text{ ml/min}$ ) was much smaller than that in beating hearts ( $0.34 \text{ ml/min}$ ). If it is assumed that the metabolic effect is independent of chronotropic and inotropic effects, the data suggest that about one-third of the increment in beating hearts could be accounted for by such a metabolic effect, at least partially dissociable from effects on work function. Recent investigations using the isolated dog heart have also indicated such a dissociation between effects of epinephrine on contractility and on oxygen consumption under somewhat different experimental conditions<sup>5,6,11</sup>.

The stimulation of glycerol release strongly suggests an increase in the rate of breakdown of glycerides or phospholipids under the influence of epinephrine. Epinephrine activation of adipose tissue lipase has been well documented<sup>7</sup>, and Randle has reported increases in FFA production in muscle on incubation with epinephrine<sup>8</sup>. Alousi and Mallov have reported increases in lipoprotein lipase activity in the hearts of rats treated chronically with epinephrine, but they did not observe any changes on acute administration of epinephrine<sup>9</sup>.

Previous investigations in this laboratory<sup>10</sup> have shown that perfusion of the rat heart with a high concentration of FFA induces an elevation of  $Q_0$ . The mechanism by which this is brought about is not as yet clear. However, these results and the present results, taken together, suggest a possible explanation for the metabolic increment in  $Q_0$  caused by epinephrine. It may be that increased breakdown of endogenous myocardial lipid, releasing FFA intracellularly, may be the initiating cause for the increase in  $Q_0$  caused by epinephrine, independently of chronotropic and inotropic effects. The latter are, of course, the

major factors leading to elevated myocardial oxygen consumption in response to epinephrine. It may be that epinephrine stimulation of lipolysis may be an important concurrent effect, providing available substrate to support the increased energy requirements of a heart beating more rapidly and more vigorously.

### Ergothioneine and Central Neurones

Crossland, Woodruff and Mitchell<sup>1</sup> have recently identified the 'cerebellar excitatory factor'<sup>2,3</sup> as ergothioneine. This factor had been found in extracts of the cerebellum from several mammalian species<sup>3</sup> and it was said to have a potent excitatory action on the electrical activity of the cerebellum and the cerebral cortex when injected into the carotid blood stream<sup>2,3</sup>. The authors therefore concluded that this factor may play a significant part in non-cholinergic synaptic transmission, in the cerebellum and other parts of the central nervous system.

We have tested the action of ergothioneine on cerebellar and cerebral cortical neurones by direct application from micropipettes. The method was similar to that used in a previous study of cerebral neurones<sup>4</sup>. The multi-barrelled micropipettes contained in one barrel a  $0.3 \text{ M}$  solution of ergothioneine hydrochloride (Koch-Light Laboratories), with the pH adjusted to a value between 4.8 and 6.5. The micropipettes were filled in a few minutes with fresh solutions, or with solutions kept frozen for several days, by centrifugation. Like the cerebellar factor<sup>3</sup>, ergothioneine is stable in acid solutions at room temperature, particularly in the absence of oxidizing agents<sup>5</sup>. The micropipettes were generally used on the day they were filled.

Four cats anaesthetized with 'Dial' compound (Ciba, Ltd.) were investigated. In each case, the micropipettes were inserted into the cerebellar cortex in several areas in and near the vermis. The action of ergothioneine was tested on a total of 70 cells firing spontaneously or as a result of excitation by small amounts of L-glutamate applied from another barrel of the pipette<sup>4</sup>. Ergothioneine was released by relatively large outward current ( $100\text{--}200 \text{ nA}$ ) for periods of at least 1 min. In most cases it did not affect significantly the excitability of the cells (Fig. 1). Approximately 1 cell in 10 showed some signs of excitation, but the effects were mostly weak and slow, requiring large doses of ergothioneine and long applications. There was no evidence that acetylcholine-sensitive cells might be more readily affected by ergothioneine, nor did the latter tend to inhibit strongly the neuronal discharge.

A number of cerebral cortical cells were also tested in two of the cats, 10 in the sensorimotor cortex, and 4 in the pyriform cortex, with even more negative results (Fig. 2).

We conclude from these observations that ergothioneine is unlikely to play a very important part as a transmitter in a widespread system of non-cholinergic synapses in the cerebellum and the cerebral cortex. This does not exclude

Fig. 1. Frequency of discharge of neurone in vermis of a cat's cerebellum. The spontaneous firing was enormously accelerated by L-glutamate, released between each pair of arrows (22 n.amp), but a large application of ergothioneine (100 n.amp), indicated by the horizontal line, had no clear action. The substances were released from different barrels of the micropipette by iontophoresis

Fig. 2. Frequency of discharge of neurone in posterior sigmoid gyrus of a cat's cerebral cortex. Between each pair of arrows, L-glutamate was released from one barrel of micropipette (40 n.amp) and during periods shown by horizontal line ergothioneine was released from another barrel (265 n.amp at first signal, 65 n.amp at second); this neither excited nor depressed the cell

the possibility that it affects neuronal function by a slower and more diffuse kind of mechanism.

### Comparison of Methods for Determination of the Sodium Content of Sweat

MEASUREMENTS of the intake and urinary output of salt under conditions of heavy sweating as obtained by Conn *et al.*<sup>1</sup>, Malhotra *et al.*<sup>2</sup> and our unit<sup>3</sup> permitted the conclusion that sodium loss in the sweat could not be as high as reported by several other authors<sup>4-6</sup>. This implies that methods employed for salt determination in the sweat give results which are considerably higher than the true salt content. The aim of the experiments reported here was to compare the reliability of these various methods.

Forty-six young men, aged 18-24, partly or fully acclimatized, and 2 farmers, aged 33 and 34, respectively, living on a 'naturalist' diet (almost devoid of sodium) were examined. Sweat was collected by three methods simultaneously: (1) Whole-body sweat (B.S.), according to the method of

von Heyningen *et al.*<sup>7</sup> with the exception that the subject was not dried throughout the experiment; (2) Arm sweat (A.S.), by enclosing the arm from the elbow down in a polyethylene bag, admixture of palm sweat being avoided by placing the hand in a rubber glove; (3) Filter paper pad sweat (P.S.) by the method reported by Dole *et al.*<sup>8</sup>.

Total sweat volume was determined by weighing the subject before and after the experiment, adding water intake and subtracting urine output. The experiments were performed in a dry fibreglass tub (160 × 160 × 60 cm). Each experiment, except four which were interrupted by the subject's inability to continue, lasted 90 min. The subjects were exercised (step test) part of the time. Climatic conditions were constant during each experiment but varied from experiment to experiment. (Dry bulb, 37°-48° C; wet bulb, 25.5°-34.5° C, relative humidity 27-48 per cent.) Double aliquots of sweat from each sample were examined for sodium by flame photometry. Results are given in m.equiv./l.

Table 1. COMPARISON OF SODIUM CONCENTRATION OF B.S. AND A.S. BY INCREASING SODIUM CONCENTRATION (IN m.equiv./l.).

m.equiv./l.	No. of subjects*	B.S.	A.S.	Difference %
5-15	10	11	19.9	79†
15.1-25	13	21.2	28.8	36†
25.1-45	16	35.1	41.9	19†

\* 7 subjects were dispersed in higher concentration groups, which were too small to be included. †  $P < 0.01$

Table 2. COMPARISON OF SODIUM CONCENTRATION OF B.S. AND A.S. ARRANGED BY RELATIVE HUMIDITY (IN m.equiv./l.).

Relative humidity	No. of subjects	B.S.	A.S.	Difference %
below 33%	8	29*	52	79†
above 33%	38	29†	36.3	25†

\* S.D. ± 13.8. † S.D. ± 15.8. ‡  $P < 0.01$

Table 3. COMPARISON OF SODIUM CONCENTRATION OF B.S., A.S. AND P.S. IN 2 'NATURALIST' FARMERS (IN m.equiv./l.).

Subject	B.S.	A.S.	P.S.	Difference B.S.-A.S. %	Difference B.S.-P.S. %
A	3.3	8.0	15.9	142	382
B	5.2	17.0	21.0	227	304

The mean sodium concentration ( $\pm$  standard deviation) in the sweat of the first 46 subjects was: B.S. 29 ( $\pm 15.6$ ), A.S. 38.5 ( $\pm 20.4$ ) and P.S. 38.4 ( $\pm 23.5$ ). Only 40 subjects were tested by the last method. Mean sodium concentration of B.S. was 33 per cent lower than by the two other methods ( $P < 0.01$ ). Differences between B.S. and A.S. were found to be highest when sodium concentration was low (Table 1) and when relative humidity was low (Table 2). Greatest differences were found in the two 'naturalists' (Table 3), who had an extremely low salt concentration (3.3 and 5.2 m.equiv./l. B.S., respectively).

The B.S. method must be considered, on theoretical and practical grounds, to be the correct one. Results by other methods are on the high side and in certain circumstances the error increased considerably. This seems to exclude the possibility of using the A.S. or P.S. methods with a corrective factor as Weiner suggested<sup>9</sup>.

The differences between the methods probably depend on multiple factors, including physiological and physical ones. Buettner has shown that water is reabsorbed by the skin when its vapour pressure in the air exceeds 21 mm Hg and when salt concentration is below 5.5 per cent<sup>10</sup>. This may account for the fact that the closer the external conditions approach the micro-climate within the bag or the pad, the smaller the differences between the methods. This would also explain Ladell's observation that no difference exists between A.S. and B.S. collected within a water-bath<sup>11</sup>.

In the experiments reported here, sodium concentration in whole-body sweat was considerably smaller than concomitantly-obtained samples of arm bag sweat and filter paper pad sweat. The difference was not constant but increased considerably with decrease of sodium in the sweat and with decrease of the relative humidity of

the air. The bag and pad methods are not suitable for determination of the sodium content of sweat.

### Oestrogen and Gonadotrophin in the Blood of Dogs during Bone Fracture Healing

PREVIOUS reports have dealt with variations in the activity of thyroid glands<sup>1</sup> and changes in the levels of androgens, follicle-stimulating and luteinizing hormones<sup>2</sup> as a result of bone fracture. The present investigation is concerned with changes in oestrogens and gonadotrophic hormones (FSH and LH) in the blood of dogs during the healing of bone fractures. Twenty-five mature anoestrous non-pregnant female dogs were used. Mid-diaphyseal fractures of the left radius were made by an open technique. Animals were anaesthetized using chlorpromazine hydrochloride and thiopental sodium. The radius in the dog was firmly fixed at its proximal and distal extremities to the ulna, which was left intact and acted as a natural splint.

At weekly intervals after fracture, 50 ml. of blood was collected by jugular venipuncture from each of 5 animals. The animals were afterwards killed and the uterus and ovaries were examined to exclude pregnancy and cyclic ovarian activity. The blood was allowed to clot, and sera belonging to animals of the same group were pooled. Groups of animals were examined at one, two, three, four and six weeks after fracture.

Oestrogenic substances were separated<sup>3</sup> and assayed biologically<sup>4</sup>. The methods used for the isolation and assay of gonadotrophic hormones were as described earlier<sup>5</sup>. The results obtained, which are shown in Table 1, were analysed statistically. The standard error of the mean was computed and 't' tests were performed to detect differences between groups.

Significantly high levels of oestrogenic substances were observed by the end of the second week after fracture and were continued until the end of the sixth week. This early rise in serum oestrogen, which was not preceded or accompanied by appreciable changes in either FSH or LH, favours the hypothesis of the existence of extra-ovarian

sources for oestrogen, such as the adrenal cortex. Adrenal corticotrophic hormone is shown to induce the production of relatively small amounts of oestrogen by the adrenals<sup>6</sup>. However, the changes in serum FSH and LH detected in the subsequent stages of the healing process could be explained on the basis of the findings which showed that oestrogen increased the synthesis and release of LH. At the same time, it induced a drop in FSH content in the blood and in the pituitary gland<sup>6</sup>. This was the case during fracture healing, where increased oestrogen formation elevated serum LH without significantly affecting serum FSH.

It is generally accepted that bone resorption takes place during the early stages of fracture healing<sup>7</sup>, this coincides with the period when the rise in serum oestrogen was insignificant. The increased level of oestrogens during the second week favours an increased bone formation<sup>8</sup> and mineral deposition<sup>9</sup>. Oestrogenic substances are known to possess a general metabolic action on bone<sup>10</sup>. It is believed that oestrogen possesses a specific stimulating effect on osteoblasts which in turn form protein matrix on which calcium and phosphorus are deposited as hydroxyapatite to form normal bone. Animal experiments have shown that ovariectomy decreased callus formation and the breaking strength of bone<sup>11</sup>. On the other hand, the extraneous administration of oestrogens hastened fracture healing<sup>12</sup>.

It could be concluded that a rise in oestrogen level takes place in the blood of dogs after the lapse of one week following bone fractures, and that this hormone is physiologically essential for the normal process of fracture repair.

### PHARMACOLOGY

#### N<sup>4</sup>-substituted N<sup>1</sup>-(3-Dimethylaminopropyl)-piperazines: a New Series of Compounds active against *Trypanosoma cruzi* Infections in Mice

RECENT reviews<sup>1-3</sup> on the treatment of *Trypanosoma cruzi* infections (Chagas's disease, South American trypanosomiasis) in man emphasize the lack of a satisfactory mode of therapy.

We wish to report the synthesis and biological evaluation of a series of compounds of the general structure:

Table 1. OESTROGENS, LUTEINIZING (LH) AND FOLLICLE STIMULATING (FSH) HORMONES IN THE SERUM OF BITCHES DURING BONE FRACTURE HEALING

Weeks after fracture	Oestrogen (mouse uterus wt., mg/100 g body-wt.)	LH (No. of corpora haemorrhagica per mouse)	FSH (wt. of mouse ovary, mg/100 g body-wt.)
Normal	63.50 ± 2.25	0.31 ± 0.170	37.14 ± 2.36
One	73.37 ± 5.66	0.20 ± 0.140	32.95 ± 3.28
Two	94.29† ± 4.16	0.10 ± 0.002	31.84 ± 2.57
Three	79.90† ± 2.36	1.27* ± 0.250	38.52 ± 3.32
Four	81.98† ± 2.15	1.36* ± 0.430	42.35 ± 3.13
Six	79.34* ± 3.50	0.50 ± 0.260	39.06 ± 2.80

± Standard error.

\* Significant at 95 per cent confidence level.

† Significant at 99 per cent confidence level.

which has shown a high degree of chemotherapeutic activity against the *B* strain of *T. cruzi* infection in mice<sup>4</sup>. Table 1 lists some of the more active members of this series and exemplifies the broad variation in *R* that is possible with minimal effect on the chemotherapeutic activity.

The compounds were usually obtained as the water-soluble hydrochloric, maleic, or fumaric acid salts. Water-insoluble 4,4'-methylenetris(3-hydroxy-2-naphthoic acid) salts of selected compounds were prepared for special investigation.

In contrast with the relative non-specificity of *R* in structure I, modifications of the *N*<sup>1</sup>-(3-dimethylamino-propyl)piperazine moiety have resulted in a considerable loss of activity against experimental *T. cruzi* infections in mice. Thus, replacement of the dimethylamino group by a diethylamino, di-isopropylamino, piperidino, or benzylmethylamino moiety, or of the 1,3-trimethylene chain by an ethylene, 1,2-propylene, or 1,4-tetramethylene chain reduced the activity to less than one-fifth of that of compound *A* (Table 1).

Screening of the compounds of structure I against *T. cruzi* was carried out as follows<sup>4</sup>: 6–8-week-old Manor strain female albino mice were inoculated subcutaneously with approximately 50,000 parasites (from infected donor mice), the median survival time of untreated mice being 13–16 days. Compounds to be tested were administered by drug-diet on days 6–12 post-inoculation. The principal criterion of chemotherapeutic activity was the survival time of treated mice relative to untreated mice, but examination of the peripheral blood and of various internal organs for parasites was also done in some experiments. Activity was unaffected when the compounds were administered by gavage, or by subcutaneous or intraperi-

toneal injection. Table 2 shows the survival data for infected mice treated with some of the compounds listed in Table 1.

The parent compound (*I*, *R* = H) was completely inactive on dosage-levels up to 512 mg/kg/day.

Compound *E* was directly compared with two compounds reported<sup>5–7</sup> to possess some activity against *T. cruzi* in mice, namely, 6-methoxy-8-(4-amino-1-methyl-butylamino) quinoline diphosphate (primaquine) and racemic 5-morpholinomethyl-3-(5-nitrofurfurylidene-amino)-2-oxazolidinone (furaltadone). The results are summarized in Table 3.

Preliminary investigations with compound *E* in the treatment of the *B* strain of *T. cruzi* infection in dogs have given favourable results. Long-term toxicity and metabolism investigations in several species of experimental animals are now being carried out.

## Mechanism of Norepinephrine Binding

A NUMBER of sympathomimetic amines chemically related to norepinephrine (Fig. 1), which have either a catechol or  $\beta$ -hydroxyl group, can be stored in the vesicles of sympathetic nerves<sup>1</sup>. Octopamine, which lacks only the *m*-hydroxyl group of norepinephrine, is released by nerve stimulation<sup>2</sup>, and is depleted by drugs which deplete norepinephrine<sup>3</sup>. Although bound to particles with similar sedimentation characteristics as those which store norepinephrine<sup>4,5</sup>, octopamine appears to be stored mainly in a compartment which has a rapid turnover.

The ability of drugs to release several sympathomimetic amines was examined in an attempt to gain insight into the role of hydroxyl groups of norepinephrine in tissue binding of this catecholamine.

Osborne-Mendel rats weighing 180–200 g received 20  $\mu$ c. of *dl*-norepinephrine-7-<sup>3</sup>H (5,600 mc./mM), 10  $\mu$ c. tyramine-<sup>3</sup>H (1,500 mc./mM), 10  $\mu$ c. of *m*-tyramine-<sup>3</sup>H (1,500 mc./mM) or 20  $\mu$ c. of dopamine-<sup>3</sup>H (3,000 mc./mM) intravenously. Animals which received dopamine were given disulphiram (400 mg/kg), 1 h prior to the labelled amine, to prevent conversion of the administered compound to norepinephrine<sup>6</sup>. Tyramine (10 mg/kg), guanethidine (20 mg/kg) or reserpine (2.5 mg/kg) was administered intramuscularly after the labelled amine, at the times indicated in Table 1. When the drugs were administered, only the  $\beta$ -hydroxylated derivatives of tyramine-<sup>3</sup>H (octopamine and *m*-octopamine) were in the hearts<sup>1</sup>. The rats were killed 2 h after administration of the labelled amines, and the hearts removed and homogenized in 10 ml. of cold 0.4 N perchloric acid. Amines present in the protein-free supernatant were analysed as previously described<sup>7,8</sup>.

As expected, tyramine, guanethidine and reserpine were not equally effective in depleting norepinephrine from the rat heart. In the interval of drug action in these experiments, tyramine depleted by 50 per cent, guan-

Fig. 1. Phenylethylamine derivatives related to norepinephrine. The structures believed to play a part in binding of the amines in sympathetic nerves are shown in bold type. Tyramine and *m*-tyramine are not retained in the tissues<sup>4,5</sup>

ethidine by 36 per cent, and reserpine by 87 per cent catecholamine (Table 1). After treatment with these drugs more dopamine, octopamine or *m*-octopamine was released. Octopamine-<sup>3</sup>H and *m*-octopamine-<sup>3</sup>H were depleted most effectively; dopamine disappearance, however, was not so great as that of the phenolic amines (Table 1). Reserpine was the most effective depleting agent for all the amines. In these experiments guanethidine appears to deplete phenolic amines more effectively than tyramine, but the two drugs appear to be equally effective in lowering tissue levels of dopamine-<sup>3</sup>H (Table 1).

These results suggest that the catechol structure and the β-hydroxyl group of norepinephrine may be important in its binding. Dopamine is less easily released than octopamine or *m*-octopamine, suggesting that the catechol group is more important than the β-hydroxyl group for resistance to depletion. Tyramine and guanethidine appear to be equally effective (at this interval of drug action) in depleting dopamine, but guanethidine is more effective in lowering tissue levels of the phenolic β-hydroxylated amines.

While it is generally agreed that there are several mathematical compartments for norepinephrine in the nerve endings<sup>9</sup> the nature of these compartments has not been defined. Crout<sup>10</sup> has suggested that the apparent compartments may be a consequence of differences in anatomical location of similar vesicles within the sympathetic nerves. The differences in turn-over rate and availability to release by tyramine are explained on the basis of differences in proximity of the vesicles to the neuronal membrane. There are alternative hypotheses, however, not based on anatomical localization, which may explain the existence of several storage sites for norepinephrine. The differential action of drugs on the release of amines related to norepinephrine suggests that chemical structure rather than anatomical location may be the determining factor in the ease of release of these amines. Different binding sites may be located in different

types of vesicles or there may be differences in the affinity of norepinephrine to several binding sites within a single vesicle. To our knowledge, no evidence has been presented which indicates that there is more than one type of vesicle for norepinephrine storage in the sympathetic nerves.

Stjärne<sup>11</sup>, however, has presented evidence that there is more than one type of norepinephrine storage in vesicles isolated from bovine splenic nerve. His results, and those presented here, suggest that the pools of norepinephrine may be related to different modes of binding of the catecholamine. Phenylethylamine derivatives may be bound through a catechol or β-hydroxyl group (Fig. 1) (ref. 1). Norepinephrine, which has both, may therefore be bound in a number of ways. This may account for the apparent pools of this catecholamine in the sympathetic nerve endings.

## PATHOLOGY

### Induction of Rat Mammary Cancers by Cancer Chemotherapeutic Agents

HUGGINS *et al.*<sup>1</sup> demonstrated that multiple mammary adenocarcinomas could be induced rapidly and invariably in female rats of the Sprague-Dawley strain by gastric instillation of 3-methylcholanthrene. Later, 7,12-dimethylbenz(a)anthracene was found to induce the same cancer<sup>2</sup>. Shellabarger *et al.*<sup>3</sup> induced similar mammary cancers in rats by sub-lethal whole-body γ-irradiation. Recently, Huggins and Fukunishi<sup>4</sup> noted that mammary carcinomas elicited either by X-irradiation or by 7,12-di-

methylbenz(a)anthracene had similar enzyme constitutions and hormone-dependency. Huggins and Yang<sup>5</sup> have postulated that both radiation and polynuclear aromatic hydrocarbons exert their oncogenic effect by selective changes in the nucleic acids of mammary cells. In an experiment described here, it was noted that mammary cancers can arise also in rats receiving anti-cancer drugs, including biological alkylating agents. Although the biological alkylating agents have been shown to induce cancers in rats, these have usually been sarcomas arising at the site of a subcutaneous injection<sup>6</sup>.

As part of an experiment designed to assess the toxicity of simultaneous carcinogen (3-methylcholanthrene) and drug administration, a group of 32 female Sprague-Dawley rats, aged 56 days, and another group of 32 rats, aged 97 days, received each of the following compounds: *N,N',N''*-triethylenethiophosphoramidate ('ThiotepaRx') 0.82 mg/kg, three times a week; methotrexate 0.29 mg/kg, three times a week; vinblastine sulphate 0.08 mg/kg, once a week; they also received cyclophosphamide ('CytoxanRx') at 0, 3.8, 7.6 or 11.5 mg/kg, and 5-fluorouracil at 0, 3.8, 7.6 or 11.5 mg/kg, three times a week. These animals did not receive polycyclic hydrocarbon carcinogen. The vinblastine sulphate was given once on each of five consecutive weeks; the other drugs were given the first, second, fourth and fifth weeks. No drug was given after the fifth week. The animals were kept in groups of 8 in stainless steel cages (separate from the group of animals which received 3-methylcholanthrene together with the anti-cancer drugs) in a well-ventilated room at 25°C. They were fed a standard chow diet with fresh lettuce three times a week and raw liver once a week. Drugs were given intraperitoneally and the amount given was based on the mean weight of the animals in each group at the start of the experiment. The animals were weighed and palpated for tumours every 10–14 days for 84 days. No tumours were detected during this interval, but appeared later in some of the animals. The animals were killed at 147 days. In the younger age group (56 days), 7 (24 per cent) of the 29 surviving rats had a total of 9 tumours; and 2 (7 per cent) of the 28 survivors in the older group (97 days) had a total of 2 tumours at the end of 147 days (Table 1). Three tumours were about 1 cm in diameter; the others were smaller. Microscopically all the tumours were mammary adenocarcinomas indistinguishable from those induced by 3-methylcholanthrene.

Table 1. INCIDENCE OF CANCERS IN TREATMENT GROUPS

Number of cancers Age-group		Thlo.	Metho.	Treatment Vinbl.	Cyclo.	5-FU
I 56 days	II 97 days					
2	0	+	+	+	0	+
0	2	+	+	+	+	0
7	0	+	+	+	+	+

The incidence of spontaneous mammary carcinomas in rats is quite low; only 1–2 per cent of rats of this strain develop such cancers over the course of a year or longer<sup>4,7,8</sup>. Thus the observed incidence of mammary cancer in this experimental group is greater than the expected spontaneous rate; moreover, the younger animals had a higher incidence than the older rats. The latter finding is especially interesting since the 50–70 day period is the time of maximum susceptibility of rats of this strain to mammary cancer induced by chemical carcinogens<sup>2</sup>. For these reasons it seems most likely that the anti-cancer drugs caused these neoplasms. It cannot be decided from this experiment which of the drugs were responsible, since all the animals received methotrexate, vinblastine sulphate and triethylenethiophosphoramidate. Two of the animals with cancers also received cyclophosphamide but not 5-fluorouracil, whereas one received 5-fluorouracil but not cyclophosphamide. The other animals received combinations of various levels of both cyclophosphamide and

5-fluorouracil in addition to the three other drugs noted here. The polyfunctional alkylating agents, cyclophosphamide and triethylenethiophosphoramidate, may be involved, since the radiomimetic effect of the nitrogen mustard alkylating agents is well known. Recently, 5-fluorouracil has been shown to have an anti-androgenic effect<sup>9</sup>, but whether this played a part in the observed carcinogenesis also remains to be established. An experiment designed to distinguish the carcinogenic effects of the drugs given singly and in combination in animals of different sex and age has been initiated.

We thank Prof. Daniel Weiss for reviewing our histological preparations. This work was supported by U.S. Public Health Service grant CA-05385 from the National Cancer Institute.

### Intracellular Location of Tissue Thromboplastin and Possible Relation to Fibrin Deposits in Human Neoplasms

IN 1958 O'Meara and Jackson<sup>1</sup>, using histochemical techniques, described deposits of fibrin in human malignant neoplasms. Fibrin has been demonstrated also in a number of experimental animal neoplasms by immunological and radioisotopic methods<sup>2,3</sup> and in a variety of human malignant neoplasms by the fluorescent antibody technique<sup>4</sup>. While fibrin may occur in haemorrhagic areas, in blood vessels and in necrotic areas in the vicinity of tumours, it also occurs in the extracellular spaces of tumours.

It is thought that the proliferating tumour cells release coagulative or thromboplastic substances which react with the proteins of the extra-cellular fluid to alter fibrinogen to fibrin. Thermolabile thromboplastins have been demonstrated in crude extracts of human malignant tumours, normal colon and normal chorion<sup>5,6</sup>. Boggust *et al.*<sup>7</sup> have isolated and investigated the properties of coagulative material from chorion and cancer tissue extracts by chromatography on DEAE cellulose and by starch-gel electrophoresis.

In order to learn more about the mechanism of fibrin deposition in tumours an attempt was made to determine the intracellular location, if any, of thromboplastic material in chorion cells with a view to a subsequent investigation of tumour cells. Chorionic membrane was chosen for the initial investigations since it does not contain blood vessels<sup>8,9</sup> and cell constituents from it are therefore unlikely to be contaminated with plasma coagulative factors.

Human placentae were collected on to saline ice immediately after delivery and the chorion was removed from the amnion. The washed chorionic membrane (22.4 g, 20 ml.) was cut into small pieces and homogenized with a glass and 'Teflon' homogenizer in 80 ml. of 0.25 M sucrose buffered to pH 7.2 with McIlvaine's phosphate citrate buffer. The homogenate (100 ml.) was passed through 16-mesh nylon bolting cloth (obtainable from Wm. Dell and Son, Ltd., 48 Weston St., London, S.E.1).

Table 1. DETAILS OF DILUTIONS OF THE PELLETS WITH 0.25 M SUCROSE TOGETHER WITH NITROGEN AND PHOSPHORUS VALUES ON THE DILUTED PELLETS. Summation of the fractions to the homogenate is also shown

Fraction	Volume of pellet (ml.)	Volume of sucrose added (ml.)	Final volume (ml.)	Nitrogen (mg/ml.)	Total nitrogen in suspended pellet (mg)	Phosphorus ( $\gamma$ /ml.)	Total phosphorus in suspended pellet (mg)
Debris and nuclear	22.5	58.3	80.8	1.25	100.4	75.5	6.10
Mitochondrial	0.5	1.3	1.8	1.25	2.25	106.5	0.19
Microsomal	0.5	1.3	1.8	3.20	5.76	484.0	0.87
Soluble			230.0	0.55	126.5	46.0	10.58
			83.9		234.9		17.75
Homogenate			84.0	2.75	251.0	212.0	17.8

After removing an aliquot (7.0 ml.) the filtered homogenate, now measuring 83 ml., was submitted to differential centrifugation<sup>10</sup> to obtain debris and nuclear fraction (700g), mitochondrial fraction (5,000g) and microsomal (57,000g) fraction. Fraction purity was checked by phase-contrast microscopy. The nuclear, mitochondrial and microsomal pellets after washing were diluted with sucrose proportional to their respective spun volumes; the details of these dilutions are shown in Table 1.

Nitrogen and phosphorus determinations were carried out on the filtered homogenate, the diluted nuclear, mitochondrial, and microsomal fractions, and also on the soluble (final supernatant) fractions. All operations were carried out at 0°–4° C and metal contact and chelating agents were avoided so far as possible.

The homogenate, suspended pellets and soluble fraction were then further diluted with 0.85 per cent saline and tested for their coagulative activity in a number of coagulation systems. Sucrose can be shown to be inert in coagulation systems and its effect is one of dilution only.

In the first system pooled human plasma was diluted 1 in 6 with 0.85 per cent saline and phosphate citrate buffer (pH 6.5) as previously described<sup>5,6</sup>; this system was designed to simulate extracellular fluid protein concentrations such as might exist in neoplasms. The calcium requirement is critical and must be titrated out beforehand for each batch of plasma<sup>5,6</sup>. 0.5 ml. of the cell fraction diluted with 0.85 per cent saline was added to 0.5 ml. diluted plasma and about 0.15 ml. of 2 per cent calcium chloride, and the highest dilution of the cell fraction giving a firm clot after 30 min at 37° C was recorded as the end point. A typical result is shown in Fig. 1.

Fig. 1. The highest saline dilutions of heated and unheated chorion cell fractions which will produce clotting in 30 min at 37° C in a recalcified dilute plasma system at pH 6.5. 'Water extract', a simple water extract of intact chorion

The diluted cell fractions were also heated at 60° C for 30 min and then tested as above, and the levels of thermostable thromboplastins are shown with the thermolabile thromboplastins in Fig. 1.

Efficient non-destructive homogenization procedures are capable of releasing very potent coagulant material from cells. The microsomal fraction (Fig. 1) shows enormous activity compared with the other fractions. The activity in the mitochondrial fraction is probably largely due to contamination by microsomes. The absence of thromboplastic activity in the soluble fraction indicates that activity is associated with a particle which is completely sedimented at 57,000g. It might be argued that the absence of activity in the soluble fraction is due to dilution by the relatively large volume of the suspending medium, but by spinning down the homogenate directly at 57,000g and sampling the supernatant for coagulative activity it can be shown that this is not the case. The relatively low activity in the homogenate may be due to an inhibitor or to physical binding of small particles.

Table 2 shows the nitrogen and phosphorus concentrations at the dilutions of greatest coagulative activity for each of the cell fractions. It will be seen that the high nitrogen and phosphorus levels in the soluble fraction are not associated with coagulative activity whereas low concentrations in the particulate microsomal fraction are associated with activity.

Table 2. NITROGEN AND PHOSPHORUS CONCENTRATIONS IN 0.5 ML. OF DILUTED CELL FRACTION AT THE HIGHEST CELL FRACTION DILUTIONS SHOWING THROMBOPLASTIC ACTIVITY, AS SHOWN IN FIG. 1

	Thermolabile titre	Nitrogen $\gamma$	Phosphorus $\gamma$
Homogenate	1,600	0.86	0.06
Nuclear	800	0.78	0.04
Mitochondrial	4,000	0.16	0.01
Microsomal	12,000	0.13	0.02
Soluble	1	275.0	23.9

The homogenate and other fractions (diluted with sucrose as described in Table 1) were then further diluted with saline, and 0.1 ml. of the dilutions were added to previously frozen platelet-free plasma and M/40 calcium in the conventional 1-stage prothrombin time of Quick. The clotting times of the various dilutions are shown in Fig. 2.

Taking the 30-sec level as a moderate degree of activity in this test it will be seen from Fig. 2 that the microsomal fraction is active at a dilution of 1/800 compared with the mitochondrial fraction (1/95), nuclear fraction (1/10), homogenate (1/30), and soluble fraction (1/4). The slope of the microsomal curve is quite different from that of the other fractions, and it is evident that these small particles retain the ability at very high dilutions to shorten the clotting time of recalcified plasma. These and other results will be reported in detail elsewhere.

Table 3. CONCENTRATIONS OF NITROGEN AND PHOSPHORUS IN 0.1 ML. OF THE DILUTED CELL FRACTIONS AT THE 30-SEC LEVEL OF THROMBOPLASTIC ACTIVITY, AS SHOWN IN FIG. 2

	Dilution	Nitrogen $\gamma$	Phosphorus $\gamma$
Homogenate	35	7.86	0.61
Nuclear	10	12.50	0.75
Mitochondrial	95	1.33	0.11
Microsomal	800	0.40	0.06
Soluble	4	13.75	1.15

Fig. 2. Clotting time of saline-diluted chorion cell fractions (0.1 ml.) when added to 0.1 ml. of previously frozen platelet-free plasma and 0.1 ml. calcium chloride (M/40). D, Difco brain thromboplastin. Saline clotting time, 85 sec. Sucrose clotting time, 110 sec. Abscissa, logarithmic scale

In Table 3 are shown the nitrogen and phosphorus levels at the 30-sec level of activity. It will be seen that the relatively high nitrogen and phosphorus levels in the particle-free soluble fraction are not associated with coagulative activity.

There has been persistent difficulty with the chemical identification of tissue thromboplastin in cells, and theoretically this could be related to a particulate nature; differential centrifugation may be useful as a preliminary step in purification. The findings here described indicate that thermolabile thromboplastic material is located principally in a minute particle in chorion cells. Preliminary observations suggest that the coagulative activity is associated with a particle rather than with soluble material.

This work was carried out initially with a grant-in-aid from the Medical Research Council of Ireland and later during the tenure of a U.S. Public Health Service post-doctoral fellowship.

## IMMUNOLOGY

### Role of Non-specific Protein in the Sensitization of Red Blood Cells by Antigen

BOTH the bis-diazotized benzidine (BDB)<sup>1</sup> and tanned cell haemagglutination<sup>2</sup> techniques are considered to be among the most sensitive methods for the detection of antibody<sup>3,4</sup>. However, whether or not both these haemagglutination techniques (BDB and tanned cells) are equally sensitive with respect to any particular anti-

Table 1. EFFECT OF PROTEIN CONCENTRATION ON THE SENSITIZATION OF RED BLOOD CELLS IN THE BDB HAEMAGGLUTINATION TECHNIQUE

BSA-anti-BSA system

0.063	128,000
0.125	128,000
0.25	128,000
0.50	128,000
1.00	128,000
1.00 + 0.25	128,000
1.00 + 0.5	128,000
1.00 + 1.0	128,000
1.00 + 2.0	32,000
1.00 + 4.0	16,000
1.00 + 8.0	8,000
1.00 + 16.0	†

\* The term 'titre' used here and in the following tables represents the maximum dilution of the antiserum capable of causing agglutination of sensitized red cells.

† Could not be determined due to non-specific agglutination.

gen-antibody system and therefore can be used interchangeably has not yet been elucidated. In fact, evidence obtained in this laboratory<sup>5</sup> would tend to suggest that, in certain cases, it is advantageous to use the BDB technique and in other cases the tanned cell technique, in order to achieve maximum sensitivity. In view of this finding, it became obvious that a better understanding of the mechanisms underlying these two haemagglutination reactions would be most appropriate. The results of initial experiments reported in this communication indicate that the two techniques differ in their ability to detect antibody when sensitization of the red cells with specific antigen is carried out in the presence of extraneous protein.

The two antigens used were bovine serum albumin (BSA) (Pentex, Inc., Kankakee, Illinois) and human  $\gamma$ -globulin (HGG) (Pentex, Inc.).

Antisera were obtained from adult New Zealand white rabbits immunized with these two antigens. The immunization schedule consisted of three 1-ml. injections, at intervals of ten days, of the antigen emulsified in complete Freund's adjuvant (Difco Laboratories, Detroit, Michigan) to a concentration of 50 mg/ml. The rabbits were bled from the marginal ear vein ten to twelve days after the last injection of the antigen. The clotted bloods were centrifuged, the sera decanted off and stored at  $-10^{\circ}\text{C}$  until used.

The BDB and tanned cell techniques were used essentially as described by Stavitsky and Arquilla<sup>1</sup>, Boyden<sup>2</sup> and Gordon *et al.*<sup>6</sup>. The sole modification in the BDB haemagglutination technique was the addition of non-specific protein (for the particular system involved) to the red-blood-cell-antigen mixture before the addition of BDB. When the tanned cell technique was used, the non-specific protein was added to the antigen prior to the addition of the tanned cells.

As can be seen in Table 2, the addition of HGG to the BSA-red-cell mixture prior to the addition of the BDB had the same effect as the addition of similar amounts of BSA (Table 1), that of markedly diminishing the antibody titre (anti-BSA) obtained with the cells sensitized with this BSA-HGG solution. This effect was especially noticeable in the presence of very large quantities of the non-cross-reactive protein (HGG) which resulted in the red cells being markedly sub-optimally sensitized with

BSA. At very high relative concentrations of HGG (16 mg), all the sensitized red cells were non-specifically agglutinated in the diluent and therefore no titre could be determined. On the other hand, even relatively small quantities of BSA were capable of completely inhibiting the sensitization of the red cells with HGG (Table 2).

With the tanned cell technique, neither BSA nor HGG was capable of inhibiting the sensitization of the cells with HGG and BSA, respectively, in the concentration used (Table 4). This result was anticipated since the optimal sensitization of the tanned cells does not appear to be dependent on the concentration of the specific antigen within the wide range of concentrations used in these experiments (Table 3).

The experiments reported in this communication were primarily concerned with the effect of non-specific protein on the sensitization of the red cell with the specific antigen. It is probable that the difficulties encountered when interpreting the results obtained with the haemagglutination techniques reside in our sparse knowledge of the mechanism of both haemagglutination techniques (BDB and tanned cell). Such information is considered to be especially important in view of the finding that, with many antisera, the BDB haemagglutination technique may give a much higher titre than that obtained with the tanned cell method (with the same antiserum) and vice versa. At times, one of the techniques may give no titre at all<sup>5</sup>.

It was demonstrated that HGG, in high concentration (HGG:BSA = 8:1), was capable of affecting the sensitization of the red cells with BSA, using the BDB technique, to the extent that the anti-BSA gave low titres when tested with the cells sensitized with this HGG-BSA solution. The effect of BSA on the HGG system was far more marked. In this case, the addition of BSA to the HGG was capable of affecting the sensitization of the cells with HGG to the extent that they would not be agglutinated in the presence of anti-HGG (Table 2). BSA was capable of exerting this effect at a relatively low concentration with respect to HGG (BSA:HGG = 2:1). On the other hand, neither the specific nor non-specific protein, in the range of concentrations used, had any adverse effect on the specific sensitization using the tanned cell technique (Tables 3 and 4). That is, HGG could not inhibit the optimal sensitization of red blood cells with BSA, even in high concentration, and vice versa. One might therefore conclude that different antigens will be affected differently, in so far as their capacity to sensitize red cells is concerned, by the presence of non-specific

protein. Furthermore, it would appear that the sensitization of red cells, using tannic acid, is less affected by extraneous protein than is the sensitization using BDB. This finding should be considered by those investigators working with organ extracts as antigens. Since these extracts are mixtures of many protein antigens, the optimal sensitization of red cells with respect to any one of these antigens may be inhibited by a heterologous protein or antigen in the solution. The results of this investigation suggest that the tanned cell haemagglutination technique would be less susceptible to non-specific inhibition of sensitization than would cells using the BDB technique.

It would therefore be advisable to use both haemagglutination techniques as screening procedures for the detection of antibodies before committing oneself as to the presence or absence of antibodies.

### Localization of Erythropoietin in Glomeruli of Sheep Kidney by Fluorescent Antibody Technique

THE kidney has been shown by several workers<sup>1-3</sup> to produce an erythropoietic substance. Investigations of the renal site of erythropoietin production, however, have been controversial and inconclusive<sup>4-6</sup>. The known antigenic properties of erythropoietin<sup>7</sup> prompted us to try a line of investigation using the fluorescent antibody technique. Anti-erythropoietin serum was prepared by injecting a young Dutch rabbit with concentrated sheep erythropoietin in complete Freund's adjuvant. (Step III Sheep Erythropoietin Lot No. K 147192 with specific activity of 11.7 units per mg protein was supplied by the U.S.P.H.S. Hematology Study Section.) 0.4 ml. of the antigen-adjuvant emulsion containing 4.8 mg (56 units) erythropoietin was injected intradermally into the footpads (0.1 ml. into each pad) of the rabbit on the first day of the investigation. One week later a second dose of 0.4 ml. (4.8 mg protein) was injected intradermally into 4 separate sites on the back of the neck. A control rabbit was also injected in the same way with Freund's adjuvant alone. Two weeks later the rabbits were bled and the sera separated.

*In vitro* activities of the antisera were determined by Ouchterlony gel-diffusion<sup>8</sup> and immuno-electrophoresis. Absorption investigations were carried out by mixing the antisera of the immunized rabbit with an equal volume of a 1:4 dilution of normal sheep serum in saline. The unabsorbed rabbit antisera contained at least 8 distinct precipitin lines when tested by immuno-electrophoresis against concentrated (24 mg protein/ml.) erythropoietin. After absorption with appropriate concentration of sheep serum only a single line was discernible.

*In vivo* neutralization of the biological activity of sheep erythropoietin was demonstrated in the polycythaemic mouse assay<sup>9</sup>. Erythropoietin-serum mixtures were mixed and left at 4° C overnight before injection into the mice. The mean per cent <sup>55</sup>Fe incorporation in red cells

Fig. 1. Fluorescence photomicrograph of rabbit kidney section treated with anti-erythropoietin serum and stained via the double sandwich method. Cytoplasmic fluorescence can be seen in the cells of the capillary walls in the glomerular tuft. ( $\times c. 200$ )

in polycythaemic mice (6 in each group) were: (a) saline,  $0.44 \pm 0.07$ ; (b) control rabbit serum mixed with 3.0 units sheep erythropoietin,  $11.5 \pm 2.2$ ; (c) unabsorbed antisera with 3.0 units erythropoietin,  $11.1 \pm 0.78$ ; (d) antisera absorbed with normal sheep serum plus 3.0 units erythropoietin,  $3.33 \pm 0.98$ . The absorbed antiserum produced a marked neutralization of the effects of 3.0 units of sheep erythropoietin on  $^{59}\text{Fe}$  incorporation in RBC of polycythaemic mice when compared with that of the control serum; while the unabsorbed antiserum did not significantly affect the biological activity of erythropoietin.

For the immuno-fluorescent investigations the 'double sandwich' method, previously used for the biological localization of renin<sup>10</sup>, in which specific antibody globulin applied to the corresponding tissue antigen is identified by means of a second layer of fluorescent anti-globulin serum, was used. Unfixed frozen sections of normal sheep kidney ( $5\mu$ ) were air-dried, treated with the antisera, washed with buffered saline, then incubated for 45 min at  $37^\circ\text{C}$  with a fluorescein isothiocyanate-labelled sheep anti-rabbit globulin serum, washed with saline, mounted in glycerol and examined with a fluorescence microscope. Fig. 1 shows the intense fluorescent staining of the capillary walls of the glomerular tuft with the absorbed antiserum. Control sections in which serum from the Freund adjuvant-injected rabbit was substituted failed to show this specific fluorescence; only the expected background fluorescence was found. Neutralization of anti-erythropoietin serum with sheep erythropoietin before the application of the antibody to the tissue reduced the glomerular staining considerably. Other capillaries not associated with glomerular tufts did not fluoresce. Treatment of sheep lung, liver and spleen by the same techniques using both absorbed anti-erythropoietin and control rabbit serum did not result in a significant amount of fluorescence. Absence of significant staining of these organs indicates that the antibody in the absorbed antiserum reacted specifically with glomeruli.

We were unable to distinguish epithelial from endothelial cells in the centre of the glomerular tuft in our preparations stained with fluorescent antibody. Therefore, it was not possible to identify the cells in the capillary wall which were reacting with the erythropoietin antibody. The juxtaglomerular area in our kidney sections did not appear to be fluorescing. However, we did not stain the juxtaglomerular cells with a tinctorial stain for granules. This does not rule out the possibility that increased fluorescence may be seen in association with the increased juxtaglomerular cell granularity reported following a potent erythropoietic stimulus<sup>5</sup>.

The results provide evidence that the site of erythropoietin elaboration is the glomerular tuft. The intense

fluorescence of the capillary wall suggests that erythropoietin is either produced or stored in these cells. The fact that the erythropoietin antibody was predominantly anti-glomerular, with complete absence of renal tubular staining, is good evidence that the renal tubules are not a site of production of erythropoietin.

### Reduction of Anaphylactic Shock in Bursectomized Chickens

IN chickens, the production of circulating antibody to soluble or bacterial antigens depends on the presence of the bursa of Fabricius (BF) during embryonic and early post-natal life<sup>1</sup>. The BF appears to have little influence on tissue immunity<sup>2</sup>.

Injections of bovine serum albumin (BSA) will induce anaphylactic shock in chickens<sup>3,4</sup>. Our data demonstrate that chemical or surgical bursectomy will suppress anaphylactic shock in chickens.

The experimental chickens were from a strain of New Hampshires developed at our Experiment Station by Prof. L. J. Dreesen. Surgical bursectomy was performed 1 day or 2 weeks after hatching. Chemical bursectomy was performed by dipping fertile eggs in 1,280 mg of testosterone propionate per 100 ml. of ethyl alcohol<sup>5</sup>. The BF obtained by bursectomy was washed with a solution of bacitracin and then immediately transferred to the subcutaneous portion of the breast of either the same chick (autotransplantation) or a different one (homotransplantation). The transplanted BF disappeared within 4 weeks and was replaced by connective tissue.

\*  $P < 0.01$ .

All birds were sensitized at 5 weeks of age with a single intravenous injection of 40 mg of BSA per kg of body-weight. A second injection of BSA, one-third the amount of the initial injection, was administered intravenously 7 days later. All birds were classified on the basis of how they responded to the second injection of BSA. A negative reaction would indicate no response. A 'slight' positive (+) response was characterized by an open beak, strenuous panting, feather fluffing, and repeated trials of defaecation. A 'mild' response (++) was recorded when the birds exhibited, in addition to these symptoms, muscular weakness, sitting on the floor and refusing to move on stimulation. A severe response (+++) included the foregoing symptoms together with convulsions. Arbitrary values of 1, 2, 3 and 4 were assigned to the slight, mild, severe and fatal (f) symptoms, respectively. The 'anaphylactic index' was calculated by multiplying the number of birds in each category by the assigned value for that category, summing, and dividing by the total number of birds<sup>6</sup>.

Removal of the BF significantly suppressed the anaphylactic symptoms (Table 1). Bursectomy at one day was more effective than at 2 weeks of age. Chemical bursectomy prevented the occurrence of anaphylactic symptoms with the exception of one chick which revealed a BF at autopsy. Neither autotransplantation nor homotransplantation was able to restore the bursectomized bird's ability to respond to a second injection of BSA.

Hypersensitivity of the delayed type is not influenced by bursectomy<sup>7</sup> while immediate hypersensitivity, anaphylaxis, is markedly reduced by bursectomy (Table 1). Once again, this emphasizes the specific part the bursa plays in avian immunity. The avian thymus significantly influences tissue immunity and has little influence on the production of circulating antibody<sup>2,8</sup>. We believe that thymectomy would significantly alter delayed hypersensitivity, but would not influence immediate hypersensitivity, anaphylaxis, in the chick.

### Effects of Antigenic Dissimilarity between Mother and Foetus on Placental Size in Mice

THE mammalian foetus must differ antigenically from its mother, in normal circumstances, the exception being in highly inbred strains. Consequently, except in matings between inbred mammals, the foetus and the foetal part of the placenta may be regarded as a homograft, and a homograft reaction against the foreign antigens might be expected. However, the antigenically different foetus and placenta are maintained in the uterus throughout pregnancy without eliciting any apparent rejection reaction, although the immunological competence of the mother must be significant during gestation.

Billington<sup>1</sup> showed that placental size tends to be greater when mother and foetus are antigenically dissimilar. He found a significantly larger size for the placentae of F1 hybrid foetuses between two inbred strains and showed, by transplantation of pure-bred eggs from one of these strains into mothers of the other strain, that this increase in size was not due to heterosis.

It was concluded that if the size of the placenta is affected by antigenic dissimilarity between mother and conceptus, this might be due to either a reaction of the maternal mucosa to the trophoblast, or a reaction of the trophoblast to a mucosa which lacks some of its antigens. An experiment was designed to investigate this problem further, and the preliminary results indicate that antigenic dissimilarity does evoke a reaction between mother and foetus, the extent of this reaction being directly proportional to the degree of immunological dissimilarity existing between them.

The mice used were young adult virgin females of the C57BL strain, mated at about 90 days of age. Four groups of mice were used. Mice of group 1 were injected, within 24 h of birth, with about 8,000,000 A2G male spleen cells in about 50  $\mu$ l. of Tyrode's solution, into the anterior facial vein, to render them tolerant. They were mated with A2G males. Mice of group 2 were injected intraperitoneally, at 6 weeks and 9 weeks of age, with half a spleen equivalent suspended in about 0.5 ml. of Tyrode's solution, to render them immune. These also were mated with A2G males. Mice of group 3 were untreated, and were mated with A2G males as controls with hybrid litters. Mice in group 4 were untreated, and mated with C57BL males as control with inbred litters.

Skin grafts were used to test tolerance and immunity, using the method of Gottfried and Padnos<sup>2</sup>. The mean survival time for the control grafts of A2G male skin on to C57BL females was found to be 10 days  $\pm$  2 days. Survival for longer than 14 days was considered as confirming tolerance, and rejection before the seventh day was considered to indicate immunity. Two animals were successfully tested in this way in group 1, and four in group 2. In these cases, tolerance and immunity, respectively, were confirmed.

The mothers were killed 17½ days after finding the vaginal plug. The placentae and foetuses were removed from the uterus, weighed and counted. Litters containing any reabsorbing foetuses were not included in the statistical analysis; and, since the size of the litter has been shown to affect individual placental size<sup>3</sup>, abnormally small litters of four or less were also excluded. Six litters were excluded on these grounds. All the remaining litters contained seven or more healthy foetuses.

The placentae were blotted on filter paper dampened with normal saline solution, and were weighed to the nearest mg on a torsion balance. The results are set out in Table 1.

Table 1

Mother	Foetus	No. of litters	No. of conceptuses	Mean size of litter	Mean wt. of placentae, and S.E., in mg
Tolerant	C57BL/A2G	8	65	8.13	88.42 $\pm$ 0.83
Immune	C57BL/A2G	9	69	7.67	111.51 $\pm$ 1.24
Control	C57BL/A2G	11	85	7.73	98.36 $\pm$ 0.76
Control	C57BL/C57BL	7	64	9.14	83.53 $\pm$ 0.78

It will be apparent that the placentae of the hybrid foetuses in group 3 are significantly larger than those of the inbred foetuses in group 4 although, since the litters of group 4 were larger, correction for litter size would tend to diminish this difference. This finding confirms Billington's claim that hybrid foetuses have larger placentae than inbred foetuses in C57BL mothers. The mean placental weights in both groups, when allowance is made for litter size, are smaller than those recorded by Billington for the same strains; a difference possibly due to variation in weighing technique.

The placentae of the tolerant group are smaller than those of the control hybrids, the difference being significant ( $P < 0.001$ ), allowance for litter size being unnecessary as it is nearly the same in both groups. Also, the placental weights of the tolerant group do not differ significantly from those of the control inbred group, and if allowance is made for difference in litter size, they would tend to be even smaller.

The placentae of the immune group are larger than those of the control hybrids ( $P < 0.001$ ), allowance for litter size again being unnecessary.

These results confirm the finding that hybrid fetuses tend to have larger placentae than pure-bred fetuses in C57BL mothers. They further show that prior immunization of the mother to the paternal antigens results in a significant increase in placental size whereas, in mothers rendered tolerant of the paternal antigens, the placentae are significantly smaller than in untreated mothers, and are indeed as small as, or possibly even smaller than, those of inbred fetuses in similar mothers.

Since the fetuses in the tolerant, immune and hybrid control groups were genetically similar with respect to the relation between mother and foetus, the observed differences in placental size must be due to the experimental condition of the mothers, depending on whether she was tolerant, immune or untreated. The tolerant mothers differ from the control mothers only in that they lack the potentiality, which the untreated mothers possess, to react to the specific foetal antigens. The difference in placental size must therefore be due primarily to this difference in the mothers. Some reaction to the foetal antigens by the control mothers, that does not take place in the tolerant mothers, must account for the differences in placental size, presumably by providing in the controls a more favourable mucosal environment for the invasion of the trophoblast than in the tolerant animals.

Pre-immunization of the mother to A2G male antigens must result in some response of the uterine tissues to the implanting hybrid embryos which enables them to establish larger placentae. Whether this response is cellular or serological in nature, or both, is unknown.

It follows that, if placental size depends on the extent of trophoblastic invasion, the latter must be affected by the maternal response in such a way that it is more extensive in immune, and less extensive in tolerant, than in untreated mothers. Histological investigation of the placentae, when this can be completed, may throw light on the mechanism involved.

I thank Prof. F. W. R. Brambell for his advice.

### Failure of some Hill Lambs to absorb Maternal Gamma-globulin

THE ability of rats to absorb proteins across the gut normally persists until 20 days of age, but can be ended earlier by the administration of certain corticosteroids<sup>1,2</sup>. As a result of this observation and an investigation of mortality data for suckling rats, it was suggested that a premature loss of absorption might be induced by mothers during stress<sup>3</sup>. Because of the severe winter of 1962-63 many hill ewes experienced long periods of undernourishment and climatic stress during pregnancy. The opportunity was taken, therefore, to examine lambs which died before weaning in hill flocks on the A.R.C. Animal Breeding

Research Organization's farms at Stanhope and Blythbank in Peeblesshire. Post-mortem examination was by the procedures described by McFarlane<sup>4</sup>. Blood samples were taken from the hearts and the serum proteins separated by electrophoresis on paper for 16 h (2 m.amp/5 cm width) in a sodium barbiturate-sodium acetate buffer (pH = 8.6;  $\mu = 0.1$ ) using 0.05 ml. serum samples. The strips were dyed with bromo-phenol blue and the concentration of each component measured with a photo-electric scanner.

Table 1. OCCURRENCE OF MILK IN THE GUT AND SERUM  $\gamma$ -GLOBULIN

Age when sampled (days)	Dead lambs without $\gamma$ -globulin		Dead lambs with $\gamma$ -globulin		Live lambs born indoors

20-24	—	—	9	20.2	4	13.9
25-43	—	—	9	18.6	5	18.5

\* Expressed as percentage of total serum proteins.

Observations were made on 259 lambs; 92 had died before, during or very shortly after birth and will not be considered further. Another 20 had died on the day of birth but had survived long enough to walk. Results from these and older lambs are summarized in Table 1, which includes, for comparison, average serum  $\gamma$ -globulin levels in healthy lambs which were born to ewes kept indoors and adequately fed during pregnancy. Normal lambs can absorb proteins only during the first 2 days of life, and any premature loss of this ability would have to be initiated *in utero*. As lambs are generally born without appreciable quantities of  $\gamma$ -globulin, the amounts of this component which have been absorbed from the colostrum can be easily determined in very young lambs, but analysis is complicated in older lambs by the presence of increasing amounts of autogenous protein.

Many of the lambs dying at ages up to 10 days had no  $\gamma$ -globulin in their sera. It would be expected that some new-born lambs would have no opportunity to suck because of desertion by the mothers or for other reasons. This partly accounts for the high proportion dying on the first day without absorbing  $\gamma$ -globulin. Over the rest of the period there were no significant differences either in the proportion with milk in the gut, or in the amount and distribution of the milk, between the groups of lambs with or lacking  $\gamma$ -globulin respectively. Some lambs dying during the first few days after birth had no milk, but low levels of  $\gamma$ -globulin; this may have been autogenous protein in some cases but in others was probably due to the ingestion of milk which was not detected at post-mortem examination. As the ages of the lambs increase, the presence of milk becomes decreasingly reliable as evidence that some was in the gut at the time when absorption normally occurs. It seems clear, however, that a considerable number of lambs obtained milk during this period yet failed to absorb any  $\gamma$ -globulin. All lambs in this category were born to Scottish Blackface ewes at Stanhope, a farm providing a particularly severe environment with mainly heather-covered hills rising to 2,700 ft. No additional features were observed which distinguished these lambs or their mothers from those of other groups.

## RADIOBIOLOGY

### Effect of Whole-body X-irradiation on $^{14}\text{C}$ -Leucine Incorporation into Proteins of Cell Nuclei of Regenerating Rat Liver

X-IRRADIATION has been shown to interfere with some biosynthetic processes in the cell nucleus of the regenerating liver. A disturbance of DNA synthesis<sup>1-3</sup> and of nuclear RNA turnover<sup>4</sup> was noted when animals were irradiated with moderate doses of X-rays in the early phase of liver regeneration (2-6 h after partial hepatectomy in the case of RNA), but no effect was observed after X-irradiation in the later stages within 24 h after operation. Similarly, an inhibitory effect of X-irradiation on the total protein turnover in the 23-h regenerating liver was reported to occur in animals exposed to lethal doses of X-irradiation 2-6 h after partial hepatectomy, but not in those irradiated 18 h after operation<sup>5</sup>. The present communication reports the effect of whole-body X-irradiation, at different time intervals within 24 h after partial hepatectomy, on amino-acid incorporation into proteins of cell nuclei isolated from a 24-h regenerating liver.

Animals used in this study were male Wistar rats of approximately 2 months and 160-170 g. Partial hepatectomies were performed according to Higgins and Anderson<sup>6</sup>. The rats were whole-body irradiated with a dose of 900 r. (measured in air), the X-ray machine operating at 220 kV and 15 m.amp., with 0.5 mm Cu and 1 mm Al. The target distance was 40 cm and the dose rate 82 r./min.

The liver was freed from erythrocytes by perfusion with cold physiological saline followed by 0.25 M sucrose-2 mM  $\text{CaCl}_2$ . The 10 per cent tissue suspension in 0.25 M sucrose-5 mM  $\text{CaCl}_2$  was treated in a hand-operated ball type homogenizer<sup>7</sup> until almost all cells were broken. Nuclei were separated from other cell fractions by repeated centrifugation in a discontinuous density gradient of 0.25 M and 0.34 M sucrose, each solution containing 2 mM  $\text{CaCl}_2$ . Nuclear suspensions in isotonic sucrose were checked for purity by phase-contrast microscopy. Those containing more than 5 per cent whole cell contaminants were rejected. Nuclei were incubated for 90 min in the presence of  $^{14}\text{C}$ -leucine (Fig. 1). After that time or at shorter intervals the reaction was stopped by adding an equal volume of 20 per cent trichloroacetic acid. Precipitated protein was purified according to Allfrey *et al.*<sup>8</sup>. Weighed aliquots were suspended in acetone and plated on Whatman No. 50 paper. The activity was counted in a gas

flow counter (Nuclear, Chicago). The results were adjusted at infinite thickness.

The time course of  $^{14}\text{C}$ -leucine incorporation into nuclear proteins during a 90-min incubation of nuclei isolated from a 24-h regenerating liver is shown in Fig. 1.

Irradiated rats received 900 r. of X-rays at 2, 6 and 16 h after partial hepatectomy. They were killed 24 h after operation. Each irradiated animal was paired with a sham-irradiated control for simultaneous incubation of nuclei. All animals were fasted from operation to killing. In these experiments the time course of  $^{14}\text{C}$ -leucine incorporation was not followed, but only 90-min incubation values were recorded. The experimental results are summarized in Table 1.

Table 1. EFFECT OF 900-R. X-IRRADIATION ON  $^{14}\text{C}$ -LEUCINE INCORPORATION INTO PROTEINS OF ISOLATED CELL NUCLEI OF 24-H REGENERATING LIVER

Time of irradiation after hepatectomy (h)	C.p.m. at infinite thickness Controls	C.p.m. at infinite thickness Irradiated	t-test
2	454 $\pm$ 33	344 $\pm$ 23	$P < 0.05$
6	432 $\pm$ 30	326 $\pm$ 26	$P < 0.05$
16	501 $\pm$ 34	499 $\pm$ 33	No difference

For each time interval eight paired rats were used.

As shown in Table 1,  $^{14}\text{C}$ -leucine incorporation into proteins of regenerating liver nuclei was inhibited by 20-25 per cent when irradiation was given 2 or 6 h after partial hepatectomy. No inhibition was observed when animals were irradiated 16 h after operation.

There is a striking similarity between the effect of X-irradiation on amino-acid incorporation at tissue level<sup>5</sup> and at nuclear level, suggesting that the mechanisms of nuclear and cytoplasmic protein synthesis are closely interdependent in growing liver cells.

### Hereditary Cataract induced by X-irradiation of Young Rats

IN a previous investigation<sup>1</sup> we showed that about 5 per cent of the offspring of 8- and 17-day-old rats which had been subject to 50, 150, 300 and 500 r. of total-body X-irradiation were dwarfs. At weaning the body-weight of the dwarf animals was half that of the controls of corresponding age, but this difference between normal and dwarfed offsprings decreased with age. In the  $F_2$  (from the  $F_1$  dwarfed generations) almost the same percentage of dwarfed animals was observed, but, in addition, in  $F_3$  some offsprings were found with bilateral cataract.

The cataracts were observed in the  $F_3$  generation of a 17-day-old female irradiated with 150 r. of total-body X-irradiation. At the age of 70 days, this female was mated with a control male and produced  $F_1$  and  $F_2$  progeny with normal eyes. In the  $F_3$  generation about 25 per cent had cataracts although all animals were not affected at the same time: at weaning about 75 per cent of the mutant offsprings showed bilateral cataracts while one or both lenses of 25 per cent appeared to be normal. At 70 days of age, bilateral cataracts were present in all mutants. The breeding tests have established that this mutation is inherited as a simple recessive factor: the mating between cataractous male and female gave 100 per cent of cataractous offspring while the mating between

Incubation medium: 1 ml. nuclear suspension, 1  $\mu\text{C}$ . DL-1- $^{14}\text{C}$ -leucine (6.4 mc./mmole), 0.20 M sucrose, 0.025 M sodium phosphate buffer (pH 7.3), 0.02 M glucose, 0.02 M NaCl, 5 mM  $\text{MgCl}_2$ , in a total volume of 2 ml.

## BIOLOGY

## Yield Depression in Wheat due to High Nitrate Applications, and its Alleviation by Molybdenum

Fig. 1. Mechanism of mutation transmission

Fig. 2. Normal and cataractous eye

an animal with cataract and a normal one resulted in a normal progeny the offsprings of which showed an incidence of cataracts in a ratio of 1/4. In the tests for detecting sex linkage, non-consistent deviation was found in the distribution of mutant animals between the sexes, and there is therefore no reason to suppose a sex-linked gene. Although the growth of the cataractous animal is normal, their fertility seems to be reduced. The transmission of this recessively inherited mutation is illustrated by Fig. 1.

For the gross dissections, the eye was cut with a razor blade and examined under a dissecting microscope. The cataractous eyes are always smaller than the normal ones (Fig. 2) and the weight of the lens is about five to ten times less than the weight of the controls at 70 days of life. Histological examination will be carried out to determine the relation between our X-ray-induced cataract mutation and the spontaneous mutations of this type described by other authors. In 1939, Bourne and Gruneberg<sup>2</sup> reported a spontaneous hereditary cataract in the rat which, however, was a recessive retinal abnormality and only one-half of the animals developed cataract after the third month. A spontaneous cataractous condition inherited as a simple dominant has also been described in the rat by Smith and Barrentine<sup>3</sup>. On the other hand, the mechanism of the development of this induced cataract will be analysed by biochemical methods to explain the role of polyol, glucose and fructose, as well as the changes in the lens cell membrane permeability, in this phenotype.

Most soils in southern Australia were initially of low nitrogen status, and bare fallows were generally used to provide mineral nitrogen for cereal crops. In more recent years a ley system based on subterranean clover (*Trifolium subterraneum* L.) pastures has been introduced to counter decline in soil fertility, weed infestation and other factors. Much higher levels of available nitrogen now occur than under previous conditions, particularly in the season immediately following the ley.

In 1962, wheat (*Triticum aestivum* L., var. 'Bencubbin') was grown on several soils in pots in the glasshouse. Four weeks after sowing, the plants developed symptoms ranging from leaf-tip scorch to death of tillers, and growth was reduced. The most severe damage occurred in plants growing on red-brown earths which had been under fallow in the field prior to collection. Eventually the plants recovered, and matured, but no measurement of the extent of damage was possible since all plants were affected.

In 1964, wheat (var. 'Bordan') was grown in pots on a yellow-brown podzolic soil on which subterranean clover was known to respond to applications of molybdenum. Sodium nitrate at four rates (0, 40, 80, 160 p.p.m. nitrogen in soil) and sodium molybdate at two rates (0, 1.5 p.p.m. molybdenum) were applied to the soil in factorial combination with nine replications, together with a basal dressing of the other essential nutrients. The plants were observed at intervals for symptoms, and after seven weeks the tops were harvested, and weighed after drying at 100° C.

Leaf damage similar to that observed in the 1962 experiment occurred in the absence of molybdenum, but not in its presence. Yields of dry matter are presented in Table 1.

Table 1. DRY MATTER YIELDS OF WHEAT PLANTS AS AFFECTED BY MOLYBDENUM- AND NITRATE-LEVELS

Nitrate treatment (p.p.m. N)	Dry matter yields (g)	
	- Molybdenum	+ Molybdenum
0	0.81	0.86
40	2.79	3.00
80	3.49	3.89
160	2.89†	4.25* ‡

\* Difference between - Mo and + Mo significant at  $P < 0.001$ .

† Difference between N 80 and N 160 in the absence of Mo significant at  $P < 0.001$ .

‡ Difference between N 80 and N 160 in the presence of Mo not significant.

In the presence or absence of molybdenum, the maximum yield was obtained with a nitrate application equivalent to 80 p.p.m. nitrogen in the soil (N 80). The higher concentration of applied nitrate depressed the yield in the absence, but not in the presence, of applied molybdenum. Where yield was depressed, the plants were chlorotic and carried many damaged leaves. At the highest rate of nitrate addition (N 160) the added molybdenum overcame not only a possible deficiency in molybdenum supply from the soil but also prevented symptoms of damage and malfunction.

A similar depression in yield and correction with molybdenum application were obtained on a red-brown earth, which would not be expected to be deficient in molybdenum<sup>1</sup>.

It is known that molybdenum is a component of nitrate reductase<sup>4</sup>. Plants supplied with nitrate require more molybdenum than plants supplied with ammonium, and nitrate accumulates in molybdenum-deficient plants<sup>5-7</sup>. The results presented here, however, show that increasing the supply of nitrate to wheat plants increases the response to applied molybdenum. The mechanism of the yield depression with high nitrate dressings and of its alleviation by application of molybdenum to the soil is not known. Among the possibilities which we are now examining

Table 2. EFFECT OF NITRATE AND MOLYBDENUM SUPPLY ON PROTEIN AND NITRATE NITROGEN IN WHEAT PLANTS

Nitrate treatment (p.p.m. N)	- Molybdenum			+ Molybdenum		
	Nitrate N (% dry matter)	Protein N (% dry matter)	Total protein nitrogen (mg/pot)	Nitrate N (% dry matter)	Protein N (% dry matter)	Total protein nitrogen (mg/pot)
0	0.02	1.63	13	0.02	1.58	14
40	0.07	1.88	52	0.03	1.69	51
80	0.13	2.50	87	0.07	1.97	77
160	0.89	3.56	103	0.50	3.42	145

are: (1) a reduction in molybdenum uptake by the plants due to the high nitrate application, as suggested by Stout *et al.*<sup>8</sup>; (2) an increased requirement for nitrate reductase, and hence for molybdenum, within the plant. The results for nitrate and total protein analyses (Table 2) suggest that there was sufficient molybdenum for nitrate reduction at least up to N 80.

At the highest level of nitrate supply (N 160), nitrate accumulated in the plants, and in the absence of applied molybdenum there was a depression in growth. It is of course possible that the nitrate concentrations in the visibly damaged tissues were much higher than the levels reported in Table 2, which refers to the whole tops.

Few responses by wheat to molybdenum applications have been reported for soil culture, so the occurrence of a response on red-brown earths is of interest because they are widely used in Australia for wheat growing.

### Glycollic Acid Metabolism and the Movements of Stomata

THE effect of carbon dioxide-free air in producing stomatal opening is well known, but practically nothing is known concerning the biochemistry of its action. Some recent work has revealed that the metabolism of glycollic acid may be implicated in stomatal movements and an attempt has been made to explain the response to low carbon dioxide tension in terms of a promotion of glycollic acid synthesis<sup>1-3</sup>. Stomatal opening in response to low carbon dioxide levels appears to have been considered purely as a light reaction; it is stated<sup>3</sup> that "low concentrations of carbon dioxide in light are necessary in order to obtain large stomatal widths". The fact is, however, that opening due to the removal of carbon dioxide can occur in the absence of light. This was observed in 1948 by Heath for *Pelargonium*<sup>4</sup>, and by several authors since, including Stålfelt<sup>5</sup>.

Recent experiments here have provided abundant evidence that the same is true in *Xanthium pennsylvanicum*. In this species some night opening occurs towards the end of a 16-h night<sup>6</sup> and this enables a stream of either carbon dioxide-free or ordinary air to be forced through the leaf. The former treatment produces quite wide stomatal opening. In Table 1 is shown, for six different leaves, the opening brought about by air free of carbon dioxide compared with that for air containing 0.03 per cent carbon dioxide. There were no humidity differences between the treatments, dry air being used in each. Another experiment (Fig. 1) demonstrated that

opening induced in this way can continue for several hours with only a small amount of re-closure. In Table 2 is shown, for six leaves, the degree of opening in white light of 15,000 lux in ordinary air compared with the maximum brought about by air free of carbon dioxide in darkness. Also shown is the degree of opening after 5 h of the latter treatment. It is not unexpected that a stream of air free of carbon dioxide through the leaf in darkness is somewhat less effective than high-intensity light for producing opening; flushing the sub-stomatal cavity cannot be expected to achieve a lowering of carbon dioxide tension as efficiently as does photosynthetic consumption within the guard cells in light of high intensity. A falling off in aperture similar to that in Fig. 1 is sometimes found in this species in light, and the behaviour in air free of carbon dioxide in darkness therefore appears to resemble quite closely the behaviour in light.

Zelitch<sup>8</sup> proposes that a glycollic acid-glyoxylic acid shuttle would oxidize pyridine nucleotides and enable photophosphorylation to proceed and provide adenosine triphosphate needed for the 'pumping' of water into the guard cells. However, since opening can occur so readily in darkness, participation of photosynthetic phosphorylation for adenosine triphosphate synthesis must be ruled out, at least in opening due to removal of carbon dioxide.

In the experiments<sup>3</sup> where high partial pressures of carbon dioxide in light were found to inhibit the synthesis of glycollic acid and also stomatal opening, the effect of the carbon dioxide was presumably to modify the products of photosynthesis in the manner which is now well established<sup>8</sup>. Stomatal opening in response to low carbon dioxide tensions is not, however, easily interpreted in terms of glycollic acid being a product of photosynthesis under such conditions. This is because opening is favoured down to extremely low carbon dioxide concentrations, and zero concentration does not cause closure<sup>9</sup>, while for glycolate production there is an optimum carbon dioxide concentration and below this, as the concentration approaches zero, production falls off<sup>10</sup>. Experiments<sup>3</sup> performed with concentrations of 1.8 per cent and 0.03 per cent representing 'high' and 'low' carbon dioxide

Table 1. STOMATAL OPENING WITH A STREAM OF AIR (0.03 PER CENT CARBON DIOXIDE) OR AIR FREE OF CARBON DIOXIDE PASSING THROUGH THE LEAF

Leaf	Dry air (0.03% CO <sub>2</sub> )	Dry CO <sub>2</sub> -free air
1	0.35	5.70
2	0.20	7.05
3	0.30	7.20
4	0.10	5.60
5	0.00	4.85
6	0.15	5.75

Leaves 1-6 represent six replications. The order of application of the two treatments was randomized. The figures indicate 'degree of opening' on the scale of the recording resistance porometer (ref. 11).

Table 2. STOMATAL OPENING IN LIGHT COMPARED WITH THAT IN AIR FREE OF CARBON DIOXIDE IN DARKNESS

Leaf	Maximum opening in 15,000 lux	Opening in CO <sub>2</sub> -free air in darkness	
		Maximum	After 5 hours
1	8.25	7.05	5.50
2	8.20	5.95	3.75
3	8.30	5.20	4.80
4	8.20	5.40	4.50
5	7.95	6.65	5.85
6	8.30	7.30	6.40

Leaves 1-6 represent six replications. The figures indicate 'degree of opening' on the scale of the recording resistance porometer (ref. 11).

Fig. 1. Stomatal opening in darkness in response to a stream of  $\text{CO}_2$ -free air passing through the leaf. Mean of observations on six leaves. Broken line indicates degree of opening in ambient air before treatment commenced. Ordinate scale: arbitrary units of total pressure minus pressure across the leaf, in a recording resistance porometer (ref. 11)

tensions are rather unsatisfactory since the stomatal response is at physiological levels<sup>9</sup>, and in light 0.03 per cent represents a 'high' concentration under natural conditions.

That there is some evidence<sup>3</sup> of glycolic acid metabolism being implicated in stomatal movements is not disputed. It is clear, however, that opening due to low carbon dioxide tensions does not depend on illumination, and this appears to rule out the mechanism so far suggested<sup>3</sup>.

I thank Dr. G. G. Pritchard (University of Exeter) and Prof. O. V. S. Heath and Dr. H. Meidner of this Department for helpful advice. This work was supported by a grant from the Agricultural Research Council.

### External Stimulus for the Natural Spawning of *Xenopus laevis*

In 1934<sup>1</sup> and 1935<sup>2</sup>, as a result of field observations and a statistical investigation of variation in the spawning date of the common frog, *Rana temporaria*, I showed that the observed relations were very unlike what would be expected if the weather were acting directly on the frogs, and suggested that the weather acted on the algae of the ponds. In 1961<sup>3</sup> a more extensive investigation lent support to this conclusion.

This work has been continued as an experimental investigation, using *Xenopus laevis*. Three aquaria, each containing about 30 l. of water, and divided into two sections by a partition, were so connected that a continuous circulation of water was maintained through them. Weed from natural ponds was placed in the upstream section from time to time. In a second series of experiments, a fourth aquarium was placed in the open air. It contained no frogs, and was used to receive the added weed. In this series, therefore, there was no physical contact between the frogs and the added weed, but the stream of water flowed through this aquarium. Temperature was kept at 23° C,

and one-half of the indoor arrangement was brightly illuminated by a fluorescent lamp, close to the water level, the other half being covered by a dark cloth. Each section contained one pair of frogs. The position of each pair was decided by a table of random numbers, and was changed once a week. In the second series, the position of the light and the presence or absence of added weed was also decided in this way. There was no substantial difference between the two series, and Table 1 is based on both. Spawning was attributed to weed when it occurred within four days from the addition, a decision based on statistical evidence that there was a peak on the second day, but that results after the fourth were rare.

Table 1

	Light		Dark		Total
	Weed	No weed	Weed	No weed	
Contribution to $\chi^2$	20 (4.25) 58.5	5 (11.75) 3.9	5 (4.25) 0.13	2 (11.75) 8.15	32 70.68

The numbers in brackets are the results expected on the null hypothesis.  $P < 0.001$ .

It can be seen that the results depart very much from chance, on the assumption that spawnings would, in that case, be distributed in proportion to the illumination and to the frequency of additions of weed. Most of the contributions to  $\chi^2$  come from the class 'weed and light', the converse 'no weed and no light' accounting for almost all the rest.

Another series of tests was then carried out, in which uni-algal cultures (usually about 3 l.) were used instead of natural collections. The cultures were of various kinds: two species of *Chlamydomonas*, a species of *Oedogonium* normally found in the aquaria, an unidentified unicellular species from a frog pond, *Chlamydomonas* cultures killed by heating to 60°, and the soil-water medium used for the *Oedogonium* and some of the *Chlamydomonas* cultures, and suspected of having activity from the algae it contained. This medium was active three weeks after sterilization. A culture of another unicellular form was not effective.

The results are shown in Table 2. In this series, there were more spawnings not associated with 'weed' than in the earlier experiments. Part way through, however, another light had been placed so that all the aquaria were illuminated, and of the 10 non-associated spawnings, 8 were from this period. Otherwise, there was little difference from the results with the mixed weed. The table is constructed on the assumption that each day constituted a trial with six replicates, whether there were any positive results or not. Since the critical period was four days, the total period of 157 days was multiplied by 6 for the grand total, and the weed occasions by 24 for the weed total. No result, positive or negative, was omitted. By the method of Fisher and Yates<sup>4</sup>,  $P < 0.005$ , so that the result is highly significant.

Table 2

	Weed	No weed	Total
	Spawn	Spawn	Spawn
No spawn	18 (9.3) 294 (302.7)	10 (18.7) 620 (614.3)	28 914
	312	630	942

$P < 0.005$

The joint action of light and weed, not necessarily in the presence of the frogs, but merely upstream from them, points to the action of a water-soluble substance, probably an algal metabolite.

The literature on the natural spawning of *X. laevis* is not extensive and is usually considered to be conflicting. Some observations by Bles<sup>5</sup> seem to have been overlooked. His paper seems to show that he sometimes added a pure culture of *Chlamydomonas* to his aquaria to induce spawning, and that he suspected that some event in the microflora influenced his animals. Vanderplank<sup>6</sup> showed the effect of light. Grimm<sup>7</sup> rightly concluded that in his experiments spawning was associated with water changes.

There was no such association in my experiments, but Grimm added filamentous algae when he changed the water in order to destroy the residual chlorine in the city water. Taken together, the present results and those in the literature appear to confirm the suggestion arrived at on the basis of the field observation on *R. temporaria*.

## ENTOMOLOGY

### Effect of 5-Fluorouracil on the Development of the Scales of *Ephestia*

THE bodies and wings of the Lepidoptera are covered with scales, which are homologous to flattened hairs. They are derived by a rather complicated mode of division and growth processes from epidermal cells. Their development in *Ephestia* has been examined in detail by Stossberg<sup>1,2</sup>. Since each scale is the product of a single cell, it might be a suitable system for the investigation of developmental mechanisms.

In a first attempt to gain some information regarding the succession of developmental events involved in the establishment of the final structure of the scale and their control mechanisms, it was decided to test the influence of 5-fluorouracil (5-FU) on the developing scale. As an analogue of uracil, 5-FU has been reported to become incorporated into RNA, thus leading to the synthesis of partially or totally modified RNA<sup>3,4</sup>.

Pupae of known ages were treated with 5-FU by implanting crystals into the body cavity. The method of implantation has been described elsewhere<sup>5</sup>. The pupae were allowed to continue development at 25° C until the 14th pupal day, when the animals were dissected. All animals were alive at this time. The front wings were dissected out, fixed shortly afterwards in 10 per cent formalin and squashed on a slide by applying gentle pressure to the overlying coverslip. The preparations were then examined under a phase contrast microscope. In each age group, 10 animals were treated and 5 more were killed immediately at the time of operation to check the developmental stage of the scales at the time of treatment.

Table 1 and Fig. 1 show briefly and schematically the normal development of the scales related to the age of the pupa as given in hours in the left column of Table 1. The Arabic numbers indicate the number of animals the scales of which have reached the stage shown in Fig. 1. The outgrowth of scales starts at 54–60 h after pupation. At 72 h, the round process flattens (stage II) and fine longitudinal elements become visible within the granular cytoplasm. At 108 h, the formation of the distal teeth is indicated (stage III). At 126–132 h, the shape is completed (stage IV) and from this time on the scale enlarges

proportionately. In stage V the cytoplasm becomes vacuolized and degenerates, leaving a rigid, fully outgrown but still unpigmented scale, which becomes strengthened by thick trabeculae (stage VI). On the 13th day, in stage VII, the pigmentation of the scale is completed<sup>1,2,6</sup>.

Table 1. NORMAL DEVELOPMENT OF SCALES ON THE WING OF *Ephestia* (Five animals for each time, stages as shown in Fig. 1)

Time after pupation (h)	No. of animals at different stages
42–48	5–0
54–60	3–0 2–I
66–72	3–I 2–II
78–84	2–I 3–II
102–108	3–II 2–III
126–132	5–IV
150–156	4–IV 1–V
174–180	5–V
198–204	5–VI
222–228	5–VI
270–276	4–VI 1–VII
294–300	5–VII

Table 2 summarizes the results obtained by implantation of 5-FU at different times after pupation as listed in the left column. It also shows the number of animals the scales of which have reached the stage indicated on the 14th day. Treatment during the 48 h following pupation completely suppresses any outgrowth. The situation changes abruptly after treatment at 54–78 h. All animals investigated possessed grown-out scales, slightly smaller than normal size, but very soft, without rigid trabeculae and of abnormal shape. The stems at the base are extraordinarily long, the distal parts frequently compressed and the teeth irregularly arranged and smaller and sharper than normal. Many of these scales show vacuolated cytoplasm. Scales of this type are illustrated in Fig. 1 without a stage number, between stages III and IV. In Table 2 they are designated by 'abnormal'. After treatment at 78–84 h, these abnormal scales are found together with normal scales of stage VI in the same preparations. Application of 5-FU to pupae older than 84 h allows the scales to differentiate further, up to stage VI or VII, depending on the time of treatment.

Table 2. DEVELOPMENT OF THE WING SCALES OF *Ephestia* AFTER TREATMENT WITH 5-FLUOROURACIL AT DIFFERENT TIMES (Ten animals in each experiment)

Time after pupation (h)	No. of animals showing different stages of scale development
42–48	10: stage 0
54–60	10: abnormal
66–72	10: abnormal
78–84	5: abnormal 5: stage VI
102–108	10: stage VI
126–132	10: stage VI
150–156	8: stage VI 2: stage VII
174–180	3: stage VI 7: stage VII
198–204	10: stage VII
222–228	10: stage VII
246–252	10: stage VII
270–276	10: stage VII

It is noteworthy that, as Table 2 shows, the reaction of the scale is an all-or-none reaction; intermediate types are absent. This seems to indicate that 5-FU interferes with a few distinct steps in the development of the scale. These steps must be assumed to initiate the proper growth and differentiation processes, since these processes themselves are not affected by 5-FU and they proceed or may even start in the presence of 5-FU.

Fig. 1. Stages in the development of scales on the fore wing of *Ephestia*. (The unnumbered sketch indicates the appearance of 'abnormal scales' induced by 5-FU at 54–84 h)

Thus, treatment with 5-FU reveals at least three clear-cut phases in the development of the scale, which initiate the successful completion of specific developmental processes: (1) The preparation for the outgrowth of the scale. This phase ends between 48 and 54 h. In the following time the growing scale may still be subjected to modification, but outgrowth cannot be suppressed by 5-FU. (2) The preparation for enlargement to full size and for the differentiation of the normal trabecular structure; this phase ends at 78–84 h. (3) The preparation for the scale pigmentation; this is completed after 180 h.

It appears, therefore, that treatment with 5-FU may have three possible results, depending on the time of treatment: it may stop the outgrowth of the scales, it may result in the formation of a characteristic type of abnormal scale, or it may permit development up to stages VI or VII. The occurrence of abnormal scales is of interest for an understanding of the possible mechanisms underlying the action of 5-FU on a developing system. It shows that the action of 5-FU does not consist only in the blocking of certain developmental steps, but also that this substance is capable of modifying the determinative processes in such a way that an abnormal structure results. It could be assumed that the normal shape of the scale, known to be under genic control, is the outcome of the synthesis of specific proteins, the formation of which is mediated by RNA. Since 5-FU has been shown to be incorporated instead of uracil in the synthesis of RNA, it is quite conceivable that, if this holds true for *Ephestia*, an abnormal RNA is being synthesized which is responsible for the synthesis of altered proteins, thus furnishing an abnormal scale. This view is consistent with the findings of Gros and Naono<sup>7</sup>, who observed the appearance of altered enzymes in *E. coli* after the addition of 5-FU. But the possibility that in the *Ephestia* system 5-FU acts by inhibition of thymidylate synthetase, and consequently affects DNA synthesis, cannot be excluded by the present experiments<sup>4,8</sup>.

## Acetylcholine as a Growth Factor in Early Larval Development of the Silkworm

ACETYLCHOLINE is required in the diet of silkworm larvae for normal moulting to occur. On a semi-synthetic basal diet (Table 1, No. 4) the newly hatched larvae die after about 14 days without further moult. In tests each using twenty larvae, it was found that the diet containing mulberry leaves (diet 1, ref. 1) yielded 100 per cent successful moult to second instar with a larval weight of 5.4 mg each; the diet with defatted soybean<sup>2,3</sup> and no other important adjuvants (diet 2) yielded 80 per cent moult (4.5 mg); the diet with royal jelly<sup>4</sup> (diet 3) yielded 100 per cent moult (5.85 mg); the basal diet without adjuvants (diet 4) yielded no moult; the basal diet with royal jelly (diet 5) yielded 70 per cent moult (4.8 mg); and basal diet plus acetylcholine (diet 6) yielded 80 per cent moult

Table 1. COMPOSITION OF ARTIFICIAL SILKWORM LARVAL DIETS

	1	2	3	4	5	6
	3.0 g	5.0 g	5.0 g	5.5 g	5.5 g	5.5 g
Cellulose powder	3.0 g	5.0 g	5.0 g	5.5 g	5.5 g	5.5 g
Casein purified	0	0	0	1.0	1.0	1.0
Soybean defatted	2.0	2.0	2.0	0	0	0
Starch	1.5	1.5	1.5	2.0	2.0	2.0
Sucrose	1.0	1.0	1.0	1.0	1.0	1.0
Minerals (Wesson's)	90 mg	90 mg	90 mg	90 mg	90 mg	90 mg
* Vitamins	40 mg	40 mg	40 mg	40 mg	40 mg	40 mg
† Stimulators	170 mg	170 mg	170 mg	170 mg	170 mg	170 mg
Mulberry powder	2.0 g	0	0	0	0	0
Royal jelly	0	0	1.5 g	0	1.5 g	0
Acetylcholine	0	0	0	0	0	5 mg
Water	15 c.c.	15 c.c.	15 c.c.	15 c.c.	15 c.c.	15 c.c.

\* A vitamin mixture composed of the following at the designated concentration in mg/10 g of diet: biotin, 0.02; Ca-pantothenate, 0.2; choline chloride, 2.0; folic acid, 0.02; niacinamide, 0.2; VB<sub>6</sub>—HCL, 0.1; VB<sub>12</sub> (FMN—Na), 0.1; VB<sub>3</sub>—HCL, 0.1; VB<sub>7</sub>, 0.1, and VC, 37.16.

† As previously pointed out<sup>7</sup>, the following compounds (especially the first) greatly stimulate the feeding reaction. The rates are identical to those listed for vitamins:  $\beta$ -sitosterol, 50; morin, 20; inositol, 50; and K<sub>2</sub>HPO<sub>4</sub>, 50.

(4.0 mg). From these results one observes that royal jelly increases moulting and larval weight. Royal jelly contains large amounts of acetylcholine<sup>5,6</sup>. A water-soluble, low-molecular-weight, dialysable fraction of royal jelly also provided similar growth stimulation. We therefore added acetylcholine to the diet<sup>7</sup> expecting the same results as with royal jelly (diet 6). As described here, acetylcholine can replace royal jelly in stimulating moulting of the larvae.

The next question concerns the optimal quantity of acetylcholine for diets, and the period during the instar when it is required. The following experiments were undertaken. (1) Feeding with the basal diet (diet 4) for all the first instar. (2) Feeding with basal diet for the first four days and then with diet 6 containing acetylcholine for the succeeding days. (3) Feeding with diet 6 for all the first instar.

Table 2. TIMING OF ACETYLCHOLINE REQUIREMENT FOR SILKWORM LARVAE

	Proportion of larvae reaching second instar (%)
No. 4 diet throughout	0
No. 4 diet for first 4 days then	
No. 6 diet for successive days	93
No. 6 diet throughout	80

Table 2 indicates that larvae do not require acetylcholine throughout the first instar, but rather addition of acetylcholine after four days of early development will provide a satisfactory growth response.

Fig. 1 shows that the larvae require more than 3,000 $\gamma$ /10 g diet for optimal growth and the threshold moulting response is between 2,000 $\gamma$  and 3,000 $\gamma$ . Acetylcholine chloride at 5 mg was used in the basal diet for the foregoing experiments, but the bromide and iodide were also

Fig. 1. Relation between dietary acetylcholine and larval moulting of first instar larvae

effective, yielding in comparable order and concentration 76, 51 and 27 per cent moult.

As summarized by Gilmour<sup>8</sup>, most insects require choline for growth. We conclude that acetylcholine or possibly other choline salts must be added in sufficient amount to semisynthetic basal diets for satisfactory growth. Insufficient levels are evidenced by inability to moult. By the addition of sufficient acetylcholine we have succeeded in rearing silkworms on an artificial diet from hatching to spinning without mulberry leaves or their extracts.

We thank Dr. K. Naito, Miss K. Matsuura, Mr. J. Nishida and Miss M. Kumazawa for their assistance, and Dr. M. Kamata (Takeda Chemical Industry Co.) for his advice. This work was supported by a grant from the Ministry of Education.

## MICROBIOLOGY

### Stimulation of Transformation by Thalidomide

At present congenital abnormalities caused by thalidomide are engaging the attention of a number of laboratories. However, only a few papers concerning the effect of the drug on protozoa and micro-organisms have been noticed so far<sup>1-3</sup>. In some cases it is difficult to analyse the effects of thalidomide because of its high instability. In neutral and aqueous solutions thalidomide is unstable with a tendency to open the phthalimide and glutarimide rings, with hydrolysis of the amide groups of phthalimide and glutarimide<sup>4</sup>. In the work recorded here the influence of thalidomide on transformation of the indole marker in *Bacillus subtilis* was examined.

An aqueous solution of thalidomide was prepared by dissolving the drug in 0.1 N KOH and then immediately neutralizing with diluted HCl so that concentration was 100 mg/ml. Directly after its dissolution thalidomide was added to the medium to a final concentration of 200 µg/ml. One general approach was made in this investigation. An attempt was made to examine the effect of thalidomide on recipient cells using the procedure of transformation by Spizizen<sup>5</sup>. To a series of tubes containing cultures of the recipient cells thalidomide was supplemented 120, 60 and 30 min before, together with and 60 min following the addition of transforming DNA. Aliquots of the culture were taken for determinations of transformation frequency 4 h after DNA was added.

Table 1

Time of treatment with thalidomide 200 µg/ml.	No. of recipient cells per ml.	Average No. transformants per ml.	Per cent transformation
0	5 × 10 <sup>8</sup>	0.2 × 10 <sup>2</sup>	0.004
3	4 × 10 <sup>8</sup>	2.4 × 10 <sup>2</sup>	0.6
4	4 × 10 <sup>8</sup>	0.2 × 10 <sup>2</sup>	0.005
4.5	3 × 10 <sup>8</sup>	3.1 × 10 <sup>2</sup>	0.1
5	4 × 10 <sup>8</sup>	5.3 × 10 <sup>2</sup>	0.066
6	8 × 10 <sup>8</sup>	5.5 × 10 <sup>2</sup>	1.37

Similar results were obtained in 4 repetitions of the foregoing experiment. Whereas in control tubes the frequency of transformation ranged from 0.002 to 0.005 per cent, in some aliquots with thalidomide it was higher than 2 per cent. To obtain a high percentage of transformants, it was found essential to supplement the drug 2 h before or 1 h following the addition of DNA to the recipient culture. The mechanism of the thalidomide effect is still obscure. It is not related to the mutagenic action of the drug. Significant differences in the number of transformants depending on the time of the drug addition suggest that the promotion of the transformation is not connected with the selection process either as a nutritional effect of thalidomide or its breakdown products. It may be assumed that the stimulation of the transformation is related to the specific effect of thalidomide on the competence of the recipient cells. Moreover, we have observed in our preliminary investigations the stimulating effect of thalidomide on the frequency of the colicinogenic factor transfer.

### Conversion of DDT to DDD by *Proteus vulgaris*, a Bacterium isolated from the Intestinal Flora of a Mouse

THE dechlorination of 2,2-bis-(p-chlorophenyl)-1,1,1-trichloroethane (DDT) to 2,2-bis-(p-chlorophenyl)-1,1-dichloroethane (DDD) by various animals has been reported recently<sup>1,2</sup>. The same detoxification reaction appears to be carried out by yeasts<sup>3</sup>. DDT administered intraperitoneally to mice was dechlorinated after, but not before, the animals were killed<sup>4</sup>. We undertook to test the hypothesis that the degradation of DDT to DDD in animals is due, at least in part, to the activity of the microflora of the gut.

Several types of micro-organism were isolated from the gut of a DDT-resistant female mouse<sup>5</sup> by serial dilution and streakplate methods on agar-brain-heart-infusion media. An ethanol solution of pure *p,p'*-DDT was placed in sterile test-tubes and evaporated over a hot-water bath. Sterile brain-heart infusion medium was then introduced into the cooled test-tubes. These preparations were inoculated with several isolates obtained from the mouse gut and the cultures were incubated for 5 days at 30° C. The contents of the tubes were extracted with methanol and chloroform<sup>6</sup>. The mixture was permitted to stand long enough to give a very clear chloroform layer. The extract was sufficiently clean to produce very clearly defined spots on paper chromatography. Paper chromatographic analysis was performed quantitatively for DDT on these extracts<sup>7</sup>.

One isolate, which was identified by morphological and biochemical tests<sup>8,9</sup> as *Proteus vulgaris*, was thus shown to dechlorinate DDT to DDD.

A culture of *P. vulgaris* (Macdonald College Culture No. 261) was obtained from the Department of Bacteriology and the experiment with the DDT-containing medium was repeated with this organism. Morphological and biochemical tests showed no significant differences between the gut isolate which produced the DDD and *P. vulgaris* from the laboratory culture. This species is associated with some diseases of animals and is one of the primary invaders of animal tissues after death<sup>10</sup>. Analysis of extracts of the media after incubation with the laboratory culture showed DDD to be the main metabolite present.

Total DDD production in the gut isolate cultures decreased in inverse proportion to the logarithm of the time of incubation, as shown in Table 1. The decrease in the total quantity of DDD produced suggests that this material is further metabolized to another product which has not yet been adequately identified.

Table 1. THE QUANTITY OF DDD PRODUCED FROM 5.45 MG OF DDT AFTER DIFFERENT PERIODS OF INCUBATION AT TWO TEMPERATURES

Time of incubation	DDD in mg 30° C	37° C
6 days	0.355	—
10 days	—	0.395
15 days	0.270	0.355
20 days	0.243	0.300

*P. vulgaris* was also grown on a medium containing 2,2-bis-(p-chlorophenyl)-1,1-dichloroethylene (DDE) but no DDD was found in extracts of these preparations. Thus as in DDT detoxification by yeasts<sup>3</sup>, DDE does not appear to be an intermediate in the production of DDD from DDT.

We conclude that the bacterium *P. vulgaris*, commonly found in the gut of mice and other animals, has the capacity of metabolizing DDT to DDD and can be assumed to be an agent, if not the sole one, in the conversion of DDT to DDD in animals which have been killed by DDT poisoning.

We thank Dr. A. C. Blackwood, Dr. R. Knowles and Dr. J. Tanner for their help.

### Isolation of the Crystalline Parasporal Bodies of *Bacillus thuringiensis*

THE method of Angus<sup>1</sup> for the isolation of parasporal bodies (crystals) from a mixture of crystals and spores has been modified so that only two treatments instead of five with fluorocarbon are necessary, and the separation can be completed in approximately 6 h. It dispenses also with the need for preliminary germination of spores.

The crystal-spore suspension is obtained by washing a crude sample as described by Angus<sup>2</sup> and is adjusted to contain 0.05 g wet wt./ml. 10 ml. of the suspension is

lightly shaken for 15 min in a 1-oz. McCartney bottle containing five drops of tri-*n*-butyl citrate and 5-g glass beads (2.0–2.5 mm diameter) by means of a Microid flask shaker (Griffin and George). The shaken suspension is transferred to the blender bottle of an MSE homogenizer containing 80 ml. 1 per cent Na<sub>2</sub>SO<sub>4</sub> solution, 1 ml. tri-*n*-butyl citrate, and 10 ml. trifluorotrichloroethane and stirred for 2.5 min at 7,700–8,000 r.p.m. The mixture is immediately transferred to a cylindrical separating funnel and allowed to stand for 15 min, when the organic phase separates out. The organic phase is discarded and the aqueous phase is centrifuged at 3,000 r.p.m. for 20 min in an MSE bench centrifuge. The deposit is taken up in a minimum of water and re-subjected to treatment with the fluorocarbon, including the shaking with glass beads. After centrifuging the separated aqueous phase, the deposit contains more than 99 per cent crystals and less than 1 per cent spores.

The deposit can be stored as an aqueous suspension or evaporated to dryness over silica gel under vacuum at room temperature, when a yield of approximately 0.2 mg/ml. of original suspension is obtained.

### Invertase Content of Yeast Protoplasts

IN 1958 three of us reported<sup>1</sup> that a large part of the invertase is liberated in a soluble state from living yeast cells (*Saccharomyces cerevisiae*) by the action of snail digestive juice. This was observed independently by Friis and Ottolenghi<sup>2</sup> and later confirmed by a number of other authors<sup>3,4</sup> although there remained some disagreement as to the extent to which protoplasts retain invertase activity.

Burger, Bacon and Bacon<sup>5</sup>, who were concerned primarily with establishing the soluble nature of yeast invertase in opposition to the views held at that time by Myrback<sup>6</sup>, stated without giving experimental data that "protoplasts isolated after 20 h (of snail juice action) and washed by centrifuging in 0.2 M lactose liberated only traces of invertase when lysed in water". Millbank<sup>4</sup>, on the other hand, like Friis and Ottolenghi<sup>2</sup> and Sutton and Lampen<sup>3</sup>, demonstrated that nearly a third of the invertase of the original cells was retained in the protoplasts. Furthermore, the protoplasts obtained from Millbank's yeast strains metabolized sucrose, without lag, at rates comparable with those of the intact cells.

A quantitative examination of the results on which these statements are based shows that no real discrepancy exists. The total invertase activity of the culture of yeast used by Burger *et al.* was almost ten times that used by Millbank. Variations of such magnitude are quite common<sup>7</sup>. Table 1 gives the results of several unpublished experiments by Burger *et al.* which show that the invertase activity of the protoplasts was in all cases of the same order as those of Millbank. However, in relation to the total activity they represented usually only 3–5 per cent 'in-

Table 1. INVERTASE ACTIVITY OF PROTOPLASTS PREPARED FROM *R XII* YEAST BY THE ACTION OF SNAIL CROP JUICE

soluble' invertase; it was perhaps something of an exaggeration to refer to this amount as 'traces'.

In view of the present discussions of the place of invertase in the economy of plant cells<sup>8</sup>, and such recent observations as those of Davies and Elvin<sup>9</sup> on the effects of  $\beta$ -mercaptoethanol on protoplast formation and invertase liberation, we thought it would be useful to remove an appearance of disagreement between ourselves on this particular point. We should also like to re-emphasize the differences which may exist between yeast strains and to stress the dangers of simple generalizations when using the term 'yeast'.

## VIROLOGY

### Stress-induced Suppression of Interferon Production in Virus-infected Mice

INCREASED susceptibility to various viruses has been observed in mice exposed to psychological stress<sup>1</sup>, in which adrenal hyperactivity is considered to be a mediator. The decrease in resistance of stressed mice to vesicular stomatitis virus (VSV) appears not to be related to impairment of antibody response<sup>2</sup>. Interferon has been proposed as an important factor in recovery from viral infections<sup>3</sup>, and interferon production in the chick embryo is inhibited by exogenous corticoid<sup>4</sup>. For these reasons, the following experiments were performed to determine whether the levels of interferon produced *in vivo* differ between stressed and unstressed mice infected with viruses.

Webster (BVR5) Swiss mice, 6-8 weeks old female, were infected intranasally with  $1 \times 10^2$ - $10^3$  plaque-forming units (P.F.U.) of VSV and divided into two groups, one of which was subjected to a high-intensity sound stress (800 c/s at an intensity-level of about 120 dB) for 3 h a day continued for 6-8 days. Under these conditions, stressed mice showed a significantly higher rate of mortality due to encephalitis caused by the VSV than had been shown earlier<sup>1,2</sup>.

At daily intervals after infection, 5 mice in each of the stressed and unstressed groups were killed by drawing blood under ether anaesthesia, and the pooled brains of each group homogenized in a glass grinder in the presence of 10 ml. Hanks's balanced salt solution without bicarbonate. The serum and brain preparations were frozen at  $-20^\circ\text{C}$  until titration for VSV-neutralizing antibody in the former, and for virus as well as interferon content in the latter. Neutralization tests and virus assays were performed on primary chick embryo fibroblasts by the plaque technique. For interferon titration, the brain homogenates were centrifuged at 32,500 r.p.m. (69,590g) for 1 h in a Spinco model L preparative ultracentrifuge. This procedure removed from the test samples all but  $1 \times 10^{-4}$  of the virus originally present before centrifuga-

tion. The residual virus in the supernate was inactivated by heating at  $56^\circ\text{C}$  for 30 min although it was found later that, unlike chick embryo interferon, which was heat-stable, this amount of heat reduced the mouse interferon activity by 30-40 per cent. The interferon preparations were serially diluted 2- to 4-fold and placed in 1.5-ml. amounts per flask (30-ml. capacity, Falcon Plastic, Los Angeles) containing primary Swiss-mouse embryo cell monolayers and incubated at  $37^\circ\text{C}$  for a period of 3 h. At the end of that time, the interferon preparations were poured off and the cells were challenged with 30-70 plaque-forming units of neurovaccinia. After 2-3 h for virus adsorption, the unadsorbed virus was removed and the cells overlaid with an agar medium containing lactalbumin hydrolysate 0.5 per cent tris 0.3 per cent, agar 0.6 per cent, and agamma calf serum 10 per cent. After further incubation at  $37^\circ\text{C}$  for 4 days, the cells were stained with neutral red and the plaques counted. The reciprocal of the highest dilution which gave 50 per cent reduction of plaque count, as compared with the control cells treated with diluent only and challenged with the same dose of virus, was reported as the titre of interferon. Overnight treatment of cells with interferon increased the titre 2-fold. Challenge with oncephalomyocarditis virus gave similar results except that the titres of interferon were lower than when neurovaccinia was used.

Fig. 1. Comparison of virus, interferon and antibody concentrations in stressed and unstressed mice infected with VSV. Unstressed,  $\nabla$ , virus;  $\square$ , interferon;  $\circ$ , antibody. Stressed,  $\blacktriangledown$ , virus;  $\blacksquare$ , interferon;  $\bullet$ , antibody. The shaded area represents the difference in values between unstressed and stressed mice.

Fig. 1 summarizes an experiment using a relatively small inoculum,  $1 \times 10^2$  plaque-forming units and 8-week-old mice in which the differences between stressed and unstressed groups were more clearly seen than in 6-week-old mice. As compared with the unstressed group, the stressed group showed an initial inhibition of virus multiplication followed by accelerated virus growth and prolonged presence of virus in the brains. Neutralizing antibody appeared on the 8th day post-infection and rose to titres of 64 at similar rates and remained the same throughout the later period of observation for both groups of mice. Interferon was detectable on the 6th day post-infection, and the maximum titre reached, 64 on the 8th day, was followed by a rapid decline in the unstressed group; whereas in the stressed group the interferon titres remained markedly low and erratic in level throughout the whole period of observation. It appears, therefore, that suppression of production of interferon rather than neutralizing antibody is important in increased susceptibility of mice subjected to these stress conditions. The negation of the initial suppression of viral multiplication in the stressed group is probably related to the suppression of interferon production, thus tipping the balance between virus multiplication and interferon production in favour of the virus. These results are in accord with those of Kilbourne *et al.*<sup>4</sup>, who showed that corticosteroids exerted an inhibition of interferon synthesis in chick embryo-influenza virus

system, because in the stressed mice increased secretion of corticoid hormone would be expected. The possibility remains, though, that stress-induced suppression of interferon production as well as higher susceptibility of mice to viral infections is mediated by systems other than the adrenal cortex. The question as to whether or not the activity of interferon as well as the rate of production *in vivo* is inhibited in the stressed as compared with the unstressed group also remains to be investigated.

The interfering activity of our preparation of interferon derived from mouse brain was destroyed by treatment with crystalline trypsin (50 µg/ml. at 37° C for 2 h) and not neutralized by anti-VSV serum. It was relatively heat-labile (56° C for 30 min), non-sedimentable in ultracentrifuge at a condition in which almost all the virus particles were spun down, active against heterologous viruses, and showed no detectable activity on chick embryo cells *in vitro*. These properties indicate that it is very similar to, if not identical with, mouse interferon as reported by others.

It was recently reported that mice infected with polyoma virus at the age of 2-3 weeks developed a higher incidence of tumours when exposed to sound stress for 3 h a day for 6 days, and then followed by avoidance-learning stress in a shuttle box for 6 h a day continued for 2 weeks, as compared with unstressed mice infected similarly<sup>5</sup>. Again the titres of serum neutralizing antibody against polyoma virus were not significantly different among the stressed and unstressed groups. The titres of virus and interferon in the organs of mice and the neutralizing antibody in the serum followed the same pattern as already described here for VSV, that is, in the stressed group there was an initial phase (4-7 days) of inhibition of growth of virus which was followed by a phase of accelerated virus multiplication with marked suppression of interferon production as compared with unstressed, polyoma virus-infected controls.

Thus, impairment of interferon production may be a significant factor in stress-induced increase in susceptibility to VSV and polyoma viruses in mice. These observations also provide further evidence for the general role of interferon in resistance to viral infections.

### A Virus as the Causal Agent of Bark Cracking in *Hevea brasiliensis*

BARK cracking accompanied by the exudation of latex (Fig. 1) in young trees of certain clones of *Hevea brasiliensis* Mull.-Arg. has been observed in the Eastern rubber-growing countries for a number of years<sup>1</sup>. The symptoms of this disorder and the accompanying histological abnor-

Fig. 1

malities have been described recently<sup>2</sup>. This is a brief note on the aetiology of the disease.

Detailed investigations, carried out at the Rubber Research Institute of Ceylon, proved that the symptoms were not caused by a bacterial or fungal infection. Anatomical abnormalities in affected plants, however, closely resembled those produced in other virus-infected woody plants<sup>3</sup>. Various methods of grafting were tested to find out whether the disease was transferable in this manner, but symptom expression following graft transfer of viruses is often long delayed. Under field conditions budded trees show symptoms of this disorder in the second and third years, and the experimental budgrafts, which are 7 months old at present, have shown only unspecific symptoms. Therefore, serological examinations<sup>4</sup> were undertaken to establish the nature of the disorder.

Antisera were prepared by injecting a clarified Seitz-filtered extract of rubber wood, from trees severely affected by the disease, into rabbits. The immunization schedule consisted of four paired intraperitoneal and intravenous injections given at 3-day intervals. The animals were bled out a fortnight after the last pair of injections. To remove possible antibodies to the normal constituents of rubber wood, the antisera were first absorbed with healthy rubber wood extracts, and the absorbed antisera were then tested by the precipitin and complement-fixation methods.

All antisera from rabbits inoculated with extracts from infected trees gave positive precipitin reactions in combination with diseased plant extracts up to a titre of 1:2,048. In complement fixation tests, the sera were tested against different dilutions of normal and infected rubber wood extracts. The antisera gave a titre of 1:640 with infected extracts, but no fixation at 1:40 dilution of normal extracts, which also showed no reaction with a 1:40 dilution of antiserum. A comprehensive series of controls was included for both types of test, using normal and infected extracts of rubber wood in combination with normal and immunized rabbit serum; all controls gave little or no reaction. These results indicate that bark cracking in young *Hevea* trees is caused by a virus

infection and not by wind damage, as suggested in an earlier publication<sup>4</sup>. A series of bud-grafting trials have been carried out to confirm these results in the field.

This is the first record of a virus disease of the *Hevea* rubber tree, although Taysum<sup>5</sup> referred to a natural virus infection of certain bacteria found in *Hevea* latex, and implied that this virus occurs normally in the latex. Investigations on the transmission of the disease under field conditions have been initiated, but for the present, as *Hevea* is a tree mainly propagated by bud-grafting, a word of warning must be sounded against the use of bud-wood from plantations which have had a history of bark cracking, as this is a likely method of disseminating this disease. Field records of the locations from which bud-wood has been selected have confirmed that bark cracking has been spread by the use of infected bud-wood in the past. A detailed account of the serological methods used here and the grafting trials carried out will be published elsewhere.

### DEAE-Chromatography of Adenoviruses of Rosen's Group II

SEVERAL antigens of adenovirus type 5 have been separated from infectious virus particles by chromatography on DEAE columns<sup>1,2</sup>. They differ in their serological specificity, and some of them have been correlated with haemagglutinins<sup>3</sup>. Differences in the elution properties between adenovirus serotypes have also been demonstrated in several instances<sup>2,4,5</sup>.

We investigated prototype adenoviruses of Rosen's group II (ref. 6), which have the common property of agglutinating rat blood cells with a complete haemagglutination pattern. Our aim was to investigate the elution properties of various viral activities and to compare the serotypes of this group with one another as well as with other adenovirus types. Type 8 was omitted from the work because of its low virus titre. Virus material from infected HeLa tissue culture fluid was treated twice with a solution of freon 112 in *n*-heptane ( $d = 1.25$ ), dialysed against 0.01 M phosphate buffer of pH 7.0 and adsorbed to columns of DEAE cellulose (Whatman, London). Elution was performed with increasing concentrations of sodium chloride (0.01, 0.05, 0.1, 0.15 M, etc.), buffered with 0.01 M phosphate buffer (pH = 7.0). Eluted material was tested for infectivity in HeLa cells, for haemagglutination with rat and (for some types) with human blood cells and for complement-fixing (CF) activity against both homologous and heterologous rabbit antisera as well as against human convalescent serum. CF tests were run with dialysed, undiluted material, a constant amount of serum (4–8 antibody units) and graded amounts of complement<sup>7</sup>.

The results are summarized in Table 1. It can be seen that the elution patterns are fairly uniform for all types of this group with only minor differences. Infectivity was found in 2–3, occasionally in more successive elution fractions, while the other antigens were mostly demon-

Table 1. RESULTS OF DEAE CHROMATOGRAPHY WITH ADENOVIRUSES OF ROSEN'S GROUP II AND WITH TYPE 5

Virus type	Elution of viral activities at indicated NaCl molarity		Infectivity
	Complement-fixing antigen	Haemagglutinin for Rat blood cells Human blood cells	
9	0.15	0.2	0.25
10	0.1	0.15	0.2
13	0.05 to 0.1	0.15	0.15
19	0.15	0.15	0.25
26	0.1	0.2	0.2
27	0.1	0.15	0.2
15	0.1	0.15	0.2
17	0.1	0.15	0.25
22	0.05 to 0.25	0.15	0.25
23	0.1	0.15	0.15
24	0.05 to 0.2	0.15	0.25
5	I: 0.01 to 0.15 II: 0.2 to 0.3	0.01 to 0.1 —	0.3 to 1.0

strated in two successive fractions only, for example, in 0.15 and 0.2 M NaCl (the first active fraction is listed in Table 1). CF activity was mostly eluted at 0.1 M NaCl, and identical reactions were found with both homologous and heterologous rabbit immune sera. Next the haemagglutinins were found in 0.15–0.2 M NaCl fractions, mostly overlapping with both CF antigen and infectivity. There was no difference in the elution pattern of haemagglutinins for rat or human blood cells. At 0.2–0.25 M NaCl infectious virus was eluted, which in most instances could be clearly separated from CF antigen, but not, or only partially, from haemagglutinin. In tests with types 22 and 26 a second peak of CF activity, eluting at higher molarities, was observed, which, however, was too low to be considered as definite. The failure to isolate a type-specific CF antigen may be due to the low antigenic strength of the material. Types 22 and 24 tended to exhibit a broader elution pattern of CF antigen than the other types.

The total quantity of viral activities eluted from the DEAE columns was 75–100 per cent of the original material for haemagglutinin, approximately 50 per cent for CF antigen, and was not determined for infectious virus.

It may be seen from the last row in Table 1 that the elution behaviour of type 5 was entirely different from that of all types of group II in all three measured activities. In contrast to the three antigens observed by Klemperer and Pereira<sup>1</sup> we found only two CF antigens, the first of type, the second of group, specificity. This discrepancy is probably due to the lower pH used by the British authors<sup>1,2</sup>. The elution of infectious virus from DEAE columns, as observed for type 8 by Haruna *et al.*<sup>4</sup> and for types 9, 10 and 15 by Zhdanov and Mekler<sup>5</sup>, corresponds well with our results. On the other hand, the notes of the Russian authors<sup>5</sup> on CF antigen and haemagglutinin are too scanty to be compared with our findings.

In a separate investigation<sup>8</sup> it was shown that group II adenoviruses fall into two sub-groups: the haemagglutinin of types 13, 26, and possibly type 23 can be separated completely from the virion by density gradient centrifugation or by adsorption to red cells. In the remaining types (9, 10, 15, 17, 19, 22, 24, 27) a virus-associated and a 'soluble' haemagglutinin is present. It is noteworthy that in the chromatographic investigation no separation of haemagglutinin and infectious virus was possible for the first sub-group (types 13, 26 and 23, Table 1), in which haemagglutinin and virion appear to have similar surface properties. On the other hand, in the second sub-group the soluble haemagglutinin was always eluted first and then virus plus virus-associated haemagglutinin. In some experiments virus fractions eluting at higher molarities were obtained without haemagglutination activity, probably because haemagglutinin was below detectable level.

Disregarding this difference, the close relationship of the virus types of group II, as indicated in Table 1, is just as striking as their dissimilarity to virus types of other adenovirus sub-groups, for example, type 5.

## ANTHROPOLOGY

### Sequence and Development of Mousterian Traditions in South-western France

THE cave and rock-shelter sites of south-western France have produced an exceptional wealth of cultural remains dating from the earlier part of the last glaciation. Much of the interest of these 'Mousterian' flint industries derives from the fact that they have frequently been found in association with neanderthal skeletal material, the evolutionary position of which is still far from settled. During the past fifteen years these assemblages have been the object of an intensive re-investigation by Prof. F. Bordes, and for this he has devised a standardized typological classification for comparing the numerous assemblages in quantitative terms. The statistical analyses provided by Bordes *et al.* have permitted the first detailed and objective comparison of French Mousterian industries, and as a result Bordes has identified five main groupings within the assemblages. These have been termed the 'Mousterian of Acheulian tradition', 'Quina', 'Ferrassie', 'Typical' and 'Denticulate' variants<sup>1</sup>.

By analogy with the Upper Palaeolithic industries of the same region one might expect that each of these variants would occur in a consistent stratigraphical position with respect to the others—in other words, occupy a specific time horizon within this region. As yet, however, no one has put forward such an interpretation and the implication is rather that the different variants represent largely contemporaneous traditions which co-existed within this area throughout much of early Würm. The purpose of the present article is to suggest that some at least of the typological patterns observed by Bordes can, in fact, be explained in more simple chronological terms and that, within the rockshelter sites of this region at least, three of the entities listed above may well be clearly separated chronologically and occur in a consistent stratigraphical order. The three variants in question are the Ferrassie, Quina and Mousterian of Acheulian tradition types, and the principal evidence for placing them in that order chronologically is discussed here briefly.

The main argument for placing the Mousterian of Acheulian tradition after the Quina variant depends on at least ten sites where characteristic cordiform hand-axes have been found stratified above Quina assemblages (Les Merveilles, La Rochette, Combe-Capelle (Bas), Pech de L'Azé, Combe-Grenal, La Quina, Roc-en-Pail, Chez-Pourré, Hauteroche, and Le Moustier (upper shelter)). Since no site appears to have produced any clear evidence of a reversal of this order, the possibility must be admitted that most—or conceivably all—of the Mousterian of Acheulian tradition assemblages are later than the Quina industries. A further argument for isolating the Mousterian of Acheulian tradition chronologically is provided by Bordes's impressive site of Combe-Grenal where, throughout five metres of rich Mousterian deposits, no trace of hand-axe industries was found<sup>2</sup>. Taken at its face

value this clearly suggests a considerable span of time during which hand-axe makers were absent from the region. These arguments, of course, apply only to the cave and rock-shelter sites of this particular area. Much earlier hand-axe/Levallois industries are well known from open sites in northern France (for example, Le Tillet) and similar sites may eventually be found farther south.

Direct stratigraphical evidence for the relationship between Quina and Ferrassie industries is more scanty but apparently consistent. At Combe-Grenal nine Quina layers were stratified above six Ferrassie levels; at the Abri Chadourne a single Quina layer was found above two Ferrassie horizons, and a similar situation probably exists at the Roc de Marsal, though full analyses for the latter site have not yet been published. The chronological separation of the Quina and Ferrassie variants is further supported by the faunal associations of the industries, which suggest much colder conditions during the time of the Quina than during the time of the Ferrassie occupation. Thus while Quina industries are generally associated with faunas in which reindeer remains are dominant (Merveilles, Hauteroche, La Quina, La Chapelle-aux-Saints, Roc-en-Pail, Roc de Marsal, Le Regourdou, Le Moustier (upper shelter)) the Ferrassie horizons of La Ferrassie (large and small abris), L'Ermitage and Les Cottés produced mainly horse and bovid remains. Relatively mild conditions at the time of the Mousterian of Acheulian tradition occupation are suggested both by the faunas (in which bovid or even red deer remains are generally dominant) and by the frequency of open air sites belonging to this tradition.

Apart from the question of the succession of the major variants discussed above, an equally interesting issue concerns the possibility of tracing any typological development which occurred within these traditions during their occupation of the Périgord region. As Bordes has pointed out, considerable typological variations exist among, for example, the various Mousterian of Acheulian tradition assemblages, and the question arises how far these variations can also be explained in chronological terms. Approaching this question initially from a purely typological point of view, a series of histograms (Fig. 1) was constructed in an attempt to arrange the various assemblages in their correct chronological order. One set of diagrams comprises the various hand-axe assemblages and in the other set the Quina and Ferrassie assemblages have been considered together. Each histogram represents one typological feature of the assemblages and in each diagram the assemblages are arranged in the same order, the suggested chronological order, from left to right.

That, with the sites arranged in this order, each diagram shows a fairly clear overall pattern or trend can scarcely be disputed and an obvious inference is that these represent the actual patterns of technological change which took place within the traditions during their occupation of the region. With regard to the Quina and Ferrassie assemblages the implication is that one develops directly into the other, thus supporting the stratigraphical and climatic evidence for the chronological separation of these two variants discussed earlier.

On the typological evidence alone, of course, the chronological interpretation of these seriation patterns is disputable. The most convincing support for such interpretations comes from sites where two or more assemblages of the same tradition have been found in a stratified succession. While fully published sites of this type are rare, the evidence from them is very satisfactory. Thus for the Ferrassie/Quina tradition the postulated trends can be checked at the Abri Chadourne and La Ferrassie (three levels each) and for the Mousterian of Acheulian tradition at Gare de Couze and Pech de L'Azé (two principal levels each). In addition to the features considered in the histograms, it is also very likely that the development of the Ferrassie/Quina tradition was characterized equally by a gradual decrease in the Levallois index. In the two three-

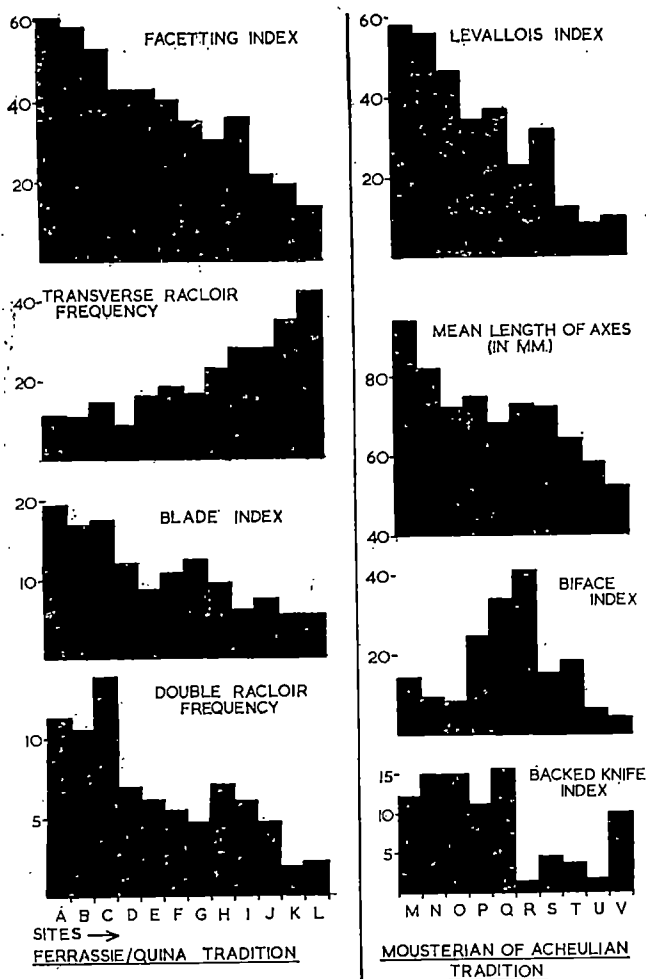

Fig. 1. Seriation diagrams for the Ferrassie/Quina tradition (left) and Mousterian of Acheulian tradition (right) in south-western France. In each histogram the assemblages are arranged in the same order—the suggested chronological order—from left to right. For the Ferrassie/Quina tradition the assemblages are: (1) L'Ermitage; (2) La Ferrassie (layer C); (3) La Ferrassie (D1); (4) Abri Chadbourne (D); (5) La Ferrassie (D2); (6) La Ferrassie, small abri; (7) Abri Chadourne (C); (8) Abri Chadourne (B); (9) Mas Viel; (10) Hauteroche; (11) La Rochette; (12) Les Merveilles. For the Mousterian of Acheulian tradition the assemblages are: (13) Abri Blanchard; (14) Gare de Couze (lower layer); (15) Gare de Couze (upper layer); (16) Combe Capelle Haute; (17) Le Mustier (layer G.); (18) Fontmaure; (19) Combe Capelle Bas; (20) Sandougnie; (21) Pech de L'Aze (lower layers); (22) Pech de L'Aze (upper layers). The tool frequencies and indices are taken from analyses according to Bordes's method. (N.B. The frequency of transverse racloirs is expressed as a percentage of all simple racloirs and not as a percentage of the total assemblage)

level sites quoted here a steady decrease in this index was clearly recorded and Bordes has stated that the same trend occurred throughout the fifteen Ferrassie and Quina layers of Combe-Grenal<sup>3</sup>. Unfortunately, the fact that this index can be considerably raised by selective collecting of unretouched flakes makes it impossible to compare directly collections from old and modern excavations on the same diagram.

The general issues of the sequence and development of early Würmian industries in south-western France discussed here are of interest from several points of view. The apparently early position of the Quina and Ferrassie industries—possibly corresponding with the post Brørup cold interval—is interesting in view of the frequency with which these assemblages have been found in association with neanderthal skeletal remains (La Quina, La Ferrassie, La Chapelle-aux-Saints, Le Regourdou, Combe-Grenal and probably Roc de Marsal). In this connexion, Brace stressed that one of the major difficulties in assessing the relationship between neanderthal and sapient forms was the lack of any clear idea of even the relative chronology

of many of the relevant neanderthal remains<sup>4</sup>. Secondly, the apparently late position of the Mousterian of Acheulian tradition lends support to Bordes's view that it was from these assemblages that the earliest Upper Palaeolithic industry of south-western France (the Chatelperronian or Perigordian 1) developed.

Of more general interest are the prospects for applying quantitative seriation methods of the type used here to flint assemblages of other periods. Similar methods—applied to collections of potsherds—have been used for some time in the New World and are useful not only for helping to construct detailed relative chronologies of sites within a limited region but also as a means of approaching the very difficult questions of the continuity or otherwise of cultural traditions in the earlier periods.

This work was supported by a Ministry of Education State studentship award.

I thank Dr. C. B. M. McBurney and Prof. J. G. D. Clark for their advice. I also thank Prof. F. Bordes, University of Bordeaux, for generous help during two visits to France.

## PSYCHOLOGY

### Role of the Olfactory System in Arousal to X-ray

It has been reliably demonstrated that rats can discriminate between the presence or absence of X-rays. Responses with latencies of less than 0.2 sec have been observed on X-rays delivered at 0.05 r./sec, where the X-ray served as the conditioned stimulus. X-rays have also served as arousing stimuli, waking sleeping or drowsy animals within 2 sec of the onset of exposure. Since these responses have been observed in ophthalmectomized animals, they are not the result of the well-known effect of ionizing radiation on the retina<sup>1-3</sup>.

The process by which X-rays elicit arousal and orienting reactions in mammals has not yet been determined. However, for simplicity we assume this mechanism operates via a 'radiation receptor'. Attempts to locate this hypothetical radiation receptor have yielded conflicting results. Some recent investigations of behavioural arousal and electroencephalographic desynchronization to X-ray have indicated a rather diffuse receptor system dispersed throughout the entire body, as well as the head of the animal<sup>4,5</sup>.

In our laboratory, on the other hand, investigations of instrumental conditioned responses to X-ray have indicated that the radiation receptor is located in the anterior region of the head and that the body of the animal is relatively insensitive to the immediate stimulating effect of X-rays<sup>6</sup>. We used a narrow 3/16-in. X-ray beam as a signal or conditioned stimulus to warn the animal of a subsequent shock to the paws. The beam was most effective when it was directed at the olfactory region of the head.

One difference between the conflicting investigations so far cited here is in the response measure used. In our work, localizing the receptor in the olfactory region, we used X-ray as a conditioned stimulus. In the work reporting more diffuse reception, the X-ray was used as an arousing stimulus. In an attempt to clarify this issue, we conducted a study of the effectiveness of X-ray as an arousing stimulus in rats the olfactory bulbs of which had been removed. De-synchronization of a previously syn-

EEG - [50  $\mu$ V

MOTOR ACTIVITY

X-RAY

2 sec

Fig. 1

Fig. 2. Percentage of arousal as a function of dose rate. Points are based on groups of 10-14 rats each receiving 4 (5-sec) exposures. The extrapolated control point is based on similar tests of 2 rats

chronized electroencephalogram (EEG) within 2 sec following the onset of the X-ray was the criterion of effective arousal. The EEG was recorded from epidural silver-silver chloride electrodes permanently implanted on the cortex of albino rats. The olfactory bulbs were removed by aspiration. Two types of control animals were prepared. In one, the cerebrum extending from bregma to the anterior tip of the hemispheres, approximately 4 mm deep block, was removed bilaterally. A small continuous portion of the midline was left intact. A second control group consisted of intact animals. Both groups were implanted with recording electrodes.

One to three weeks after surgery, all animals were first tested for sensitivity to X-ray. For radiation exposure, the animals were confined to a small plastic chamber enclosed in a larger acoustically and electrically shielded wooden box. The floor of the box was mounted on springs. The movements of the animal were converted into an electrical signal by a crystal pickup and recorded on an EEG channel. The interior of the box was well lighted and equipped with a speaker emitting a continuous wide-band masking noise. The box was placed so that the plastic chamber was directly under the X-ray machine (250 kV; 0.5 mm copper filter, 1.7 mm copper half-value layer). Output was measured by a Victoreen chamber placed in the plastic chamber. The technique for exposure of the animal to X-ray has been previously described<sup>2</sup>. It permits all other potential stimuli to be held constant during exposure to X-rays. In addition, all animals were tested with sham exposures identical to X-ray exposures except that a lead plate, inserted in place of the copper filter in the X-ray machine, reduced the radiation dose to zero. All sham and X-ray exposures were of 5-sec duration. Each animal was given 4 sham

and 4 X-ray exposures at each dose rate. Some experimental and control animals were tested with more than one dose rate. In such cases more than a week elapsed between the two test series.

X-ray exposure which produced a prompt arousal (Fig. 1) in control animals had little effect on the animals without olfactory bulbs. Fig. 2 summarizes the results. The frequency of animals exhibiting one or more arousals was statistically greater ( $P < 0.01$ ) for control groups than for the comparable experimental groups at the 0.5 r. and 1.0 r./sec dose rates. Since the lower dose rates (0.5, 1.0 r./sec) produced a high proportion of arousals in the control animals, a control group at the highest

dose rate (2.5 r./sec) appeared superfluous. Two animals tested at 2.5 r./sec exhibited intense reactions to the increased dose rate as was expected. The highest dose rate (2.5 r./sec) appeared to produce a slightly greater number of arousals in the anosmic animals as well (Fig. 2).

The results indicate a distinct loss of sensitivity when the olfactory bulbs are removed. This agrees with our previous work<sup>4</sup> in which a collimated X-ray beam was used as a conditioned stimulus to demonstrate a maximum sensitivity in the region of the olfactory bulbs. The two methods agree in locating the radiation receptor in the olfactory system. At present we are unable to reconcile our results with reports that both the head and body are sensitive to X-ray at the dose-levels we have reported here. Our control animals with relatively large cerebral lesions were all able to detect X-rays. On the other hand, animals with olfactory lobectomies, while insensitive to X-rays, appeared to arouse as readily to auditory stimuli as did controls. This makes it unlikely that a generally decreased sensitivity due to damage to the nervous system can explain the data.

While the 'specifics' of X-ray detection remain to be determined, the effect does not appear to depend on the smelling of ozone. When the collimated beam was directed through the nasal and oral passages anterior to the olfactory bulb, it was relatively ineffective. (Note added in proof. Five rats with chronic tracheotomies, which prevented nasal inhalation of ozone or any other radiation by-product, all aroused to X-ray.)

In the work recorded here the number of arousals in the anosmic animals was small, but there is an apparent correlation with intensity or dose rate. This may indicate that our animals were not completely anosmic, or it may mean that other receptor systems were stimulated. It seems plausible that other receptor systems could be activated if higher dose rates and longer durations were used.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, February 8

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 4 p.m.—Dr. B. Ackner: "Organic Mental Syndromes".\*

BRITISH SOCIETY FOR THE PHILOSOPHY OF SCIENCE (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. H. Bondi, F.R.S.: "The Disproof of Theories".

UNIVERSITY OF LONDON (in the Physiology Department Theatre, St. Bartholomew's Hospital Medical College, West Smithfield, London, E.C.1), at 5.30 p.m.—Prof. K. J. Ullrich: "Characteristics of Renal NaCl-transport, and its Modification by Aldosterone and Saluretic Sulphonamides".\*

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, W.C.2), at 6.30 p.m.—Mr. B. W. Leyland: "Earth Return Applied to High Voltage Systems".

ROYAL AERONAUTICAL SOCIETY, HISTORICAL GROUP (at 4 Hamilton Place, London, W.1), at 7 p.m.—Sqn./Ldr. S. C. Winfield Smith: "British Aviation Fifty Years Ago".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. J. B. Ward Perkins, C.B.E.: "The Changing Historical Landscape of Italy".

## Monday, February 8—Tuesday, February 9

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2)—Conference on "Electronics Design".

## Tuesday, February 9

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "The Effect of Variations in Supply Voltages in Industrial Processes" opened by Mr. J. A. Tatchell and Mr. H. J. Sheppard.

INSTITUTION OF THE RUBBER INDUSTRY, LONDON SECTION (at the Royal Society of Tropical Medicine, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. A. P. Riding: "Rubber Products used in the Printing Industry". 7 p.m.—Mr. V. N. Chatterton: "New Application Developments with Viton Fluoroelastomers".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. G. W. Harris: "Central Nervous Regulation of the Pituitary Gland". (Eighth of sixteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)\*

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMOBILE DIVISION (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. J. E. Robinson: "The Design and Development of Pistons for Automobile Engines".

ROYAL AERONAUTICAL SOCIETY, ASTRONAUTICS AND GUIDED FLIGHT SECTION (at 4 Hamilton Place, London, W.1), at 6 p.m.—Mr. J. G. Walker: "Communications Satellites".

ROYAL SOCIETY OF MEDICINE, PSYCHIATRY SECTION (at 1 Wimpole Street, London, W.1), at 8 p.m.—Meeting on "The Assessment of Methods of Psychological Treatment". Speakers: Dr. D. H. Malan and Dr. M. G. Gelder.

## Wednesday, February 10

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 2 p.m.—Prof. G. V. R. Born: "Platelet Aggregation".\*

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. E. V. D. Glazier: "Radar—Present Position and Future Trends".

UNIVERSITY OF LONDON (at the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2), at 5.30 p.m.—Prof. D. J. Anderson: "Science in Dentistry". (First of three lectures on "The Scientific Basis of Dentistry" organized by the British Postgraduate Medical Federation.)\*

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, JOINT I.E.E./I.E.R.E. MEDICAL ELECTRONICS GROUP (at 9 Bedford Square, London, W.C.1), at 6 p.m.—Discussion on "Safety of Operating Theatre Equipment".

INSTITUTION OF MECHANICAL ENGINEERS, APPLIED MECHANICS GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. K. Saxl: "The Pendulum Mill—a New Method of Rolling Metals".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Dr. R. W. G. Hunt: "Recent Developments in Colour Photography" (Peter Le Neve Foster Lecture).

SOCIETY OF INSTRUMENT TECHNOLOGY (at Manson House, 26 Portland Place, London, W.1), at 6 p.m.—Mr. F. I. L. Knowles and Mr. D. N. Gascoyne: "Measurement of Transient Events in Armaments Research".

SOCIETY OF CHEMICAL INDUSTRY, MICROBIOLOGY GROUP AND NUTRITION PANEL (Food Group) (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Dr. G. D. Rosen: "The Microbiological Assay of Protein Quality".

OFFICE OF HEALTH ECONOMICS (at the Royal Society of Health, 90 Buckingham Palace Road, London, S.W.1), at 8.30 p.m.—Mr. G. Teeling-Smith: "The Role of Marketing in Scientific Progress".\*

## Thursday, February 11

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 10.30 a.m.—Discussion Meeting on "Pion-Nucleon Scattering and Excited Nucleon States" organized by Prof. R. H. Dalitz, F.R.S.

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. K. Vickerman: "Developing Africa; the Biologist's Dilemma".\*

INSTITUTION OF CIVIL ENGINEERS, TRANSPORTATION ENGINEERING GROUP (at Great George Street, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Operational Research as Applied to Transportation" introduced by Mr. P. I. Welding.

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "The Electrometer Amplifier—Its Design and Applications" opened by Mr. G. I. Hitchcox and Mr. G. R. Taylor.

UNIVERSITY COLLEGE, LONDON (in the Physiology Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. W. Feldberg, F.R.S.: "A New Concept of Temperature Regulation in the Hypothalamus".\*

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. S. Shaldon: "Long-Term Haemodialysis as a Substitute for Kidney Function". (Ninth of sixteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)\*

UNIVERSITY OF LONDON (in the Physiology Department Theatre, St. Bartholomew's Hospital Medical College, West Smithfield, London, E.C.1), at 5.30 p.m.—Prof. K. J. Ullrich: "Micropuncture Studies of Salivary and Sweat Glands".\*

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION AND TRAINING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Should there be Less Specialization in University Courses?".

SOCIETY FOR ANALYTICAL CHEMISTRY, BIOLOGICAL METHODS GROUP (at "The Feathers" Restaurant, Tudor Street, London, E.C.4), at 6.45 p.m.—Mr. B. Collier: "Methods of Estimating Activities of Commercial Enzymes".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION, KENT SUB-SECTION (at the Bull Hotel, Rochester, Kent), at 7 p.m.—Mr. K. C. Bryant: "Polymers from Petroleum".

## Friday, February 12

ASSOCIATION OF APPLIED BIOLOGISTS (in the Lecture Hall of the British Museum (Natural History), Cromwell Road, London, S.W.7), at 10.50 a.m.—Symposium on "Soil Sterilization".

INSTITUTE OF NAVIGATION (at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1), at 5.30 p.m.—Captain C. J. Wennink: "Problems of Ice Navigation with Modern Tankers".

INSTITUTION OF MECHANICAL ENGINEERS, APPLIED MECHANICS GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Use and Abuse of Ultra-High-Strength Steels".

ASSOCIATION OF CLINICAL BIOCHEMISTS, SOUTHERN REGION (at "The Feathers Inn", 34 Tudor Street, London, E.C.4), at 7 p.m.—Discussion Meeting devoted to Professional Affairs.

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the Sir John Cass College Chemical Society, at Sir John Cass College, Jewry Street, London, E.C.3), at 7 p.m.—Prof. J. Chatt, F.R.S.: "Stabilization of Low Valent States of the Transition Metals".

ROYAL INSTITUTE (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. A. F. Huxley, F.R.S.: "Muscle Fibres Under the Microscope".

## Monday, February 15

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 3 p.m.—Colloquium on "Design of Solid State Power Supplies".

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. A. J. Clarke: "Hatching Agents for Cyst-Forming Nematodes".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER or ASSISTANT LECTURER in PURE or APPLIED MATHEMATICS—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8 (February 13).

SENIOR LECTURER in MAMMALIAN PHYSIOLOGY in the DEPARTMENT of BIOLOGICAL STUDIES—The Principal, Lanchester College of Technology, Priory Street, Coventry (February 15).

LECTURER (specializing in statistical or solid state theory) in THEORETICAL PHYSICS—The Registrar, King's College (University of London), Strand, London, W.C.2 (February 19).

ASSISTANT LECTURER (with a good honours degree in electrical engineering or physics, with special interests in control, materials or communications) in the DEPARTMENT of ELECTRICAL ENGINEERING—The Secretary, The University, Edinburgh (February 20).

LECTURER in ASTRONOMY—The Registrar, The University, Leicester (February 20).

LECTURER or ASSISTANT LECTURER in the DEPARTMENT of APPLIED MATHEMATICS—The Registrar, The University, Liverpool, quoting Ref. CV/376 (February 20).

LECTURER or ASSISTANT LECTURER in EXPERIMENTAL PHYSICS, and a LECTURER or ASSISTANT LECTURER in THEORETICAL PHYSICS—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (February 22).

LECTURER or ASSISTANT LECTURER in the DEPARTMENT of MICROBIOLOGY, and an ASSISTANT LECTURER (preferably with experience in spectroscopy, X-ray diffraction or electron microscopy) in the DEPARTMENT of PHYSICS—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8 (February 22).

LECTURER (physicist or physical chemist) in the DEPARTMENT of PHYSICS to assist with the teaching of the degree course in the physical properties of materials—The Registrar (Room 22, O.R.B.), The University, Reading (February 22).

ASSISTANT LECTURER in the DEPARTMENT of GEOGRAPHY—The Assistant Secretary, London School of Economics and Political Science, Houghton Street, London, W.C.2 (February 25).

ASSISTANT LECTURER or LECTURER in PSYCHOLOGY—The Registrar (Room 22, O.R.B.), The University, Reading (February 27).

**ELECTRON MICROSCOPIST** (with a first- or good second-class honours degree in chemistry or physics with post-graduate research experience in X-ray or electron diffraction, a knowledge of diffraction theory as applied to structural crystallography, and preferably some familiarity with biological applications of electron microscopy) IN THE DEPARTMENT OF PEDOLOGY—The Secretary, Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (February 27).

**GEORGE HOLT CHAIR OF PATHOLOGY**—The Registrar, The University, Liverpool (February 27).

**LECTURER** (with field work experience) IN THE DEPARTMENT OF SOCIAL ANTHROPOLOGY—The Secretary, The University, Edinburgh (February 28).

**CHAIR OF APPLIED MATHEMATICS**—The Registrar, The University, Sheffield (March 1).

**CHAIR OF MATHEMATICS**—The Registrar, The College of Aeronautics, Cranfield, Bedford (March 1).

**CHAIR OF PSYCHOLOGY**—The Registrar, University College of Swansea, Singleton Park, Swansea (March 1).

**LECTURER IN THE DEPARTMENT OF BIOLOGICAL CHEMISTRY**—The Secretary, The University, Aberdeen (March 1).

**RESEARCH FELLOW** (with a degree in soil science or agriculture with some postgraduate experience, preferably in tropical soils) IN THE DEPARTMENT OF CROP HUSBANDRY AND HORTICULTURE, University of Ghana—The Assistant Registrar, University of Ghana Overseas Office, 15 Gordon Square, London, W.C.1; or The Registrar, University of Ghana, P.O. Box 25, Legon, Accra, Ghana (March 3).

**LECTURER IN ORGANIC CHEMISTRY**—The Secretary, The University, Aberdeen (March 6).

**READER IN ENGINEERING GEOLOGY**—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (March 7).

**CHAIR OF STRUCTURAL ENGINEERING WITHIN THE DEPARTMENT OF CIVIL ENGINEERING**—The Registrar, University of Strathclyde, George Street, Glasgow, C.1 (March 12).

**CHAIR OF STATISTICS**—The Registrar, University of Kent at Canterbury, Westgate House, Canterbury (March 15).

**LECTURER IN ZOOLOGY**—The Secretary, The University, Aberdeen, Scotland (March 15).

**LECTURER** (preferably with a knowledge of physiology) IN PHYSIOLOGICAL CHEMISTRY with special reference to Biochemistry; and a LECTURER IN PHYSIOLOGICAL CHEMISTRY with special reference to Physiology—The Registrar (Room 22, O.R.B.), The University, Reading (March 16).

**ASSISTANT LECTURER** (with a good honours degree) IN THE DEPARTMENT OF APPLIED MICROBIOLOGY AND BIOLOGY—The Registrar, University of Strathclyde, George Street, Glasgow, C.1.

**LIBRARIAN** (Chartered Librarian, with a working knowledge of at least one foreign language, and preferably experience of scientific literature) at Long Ashton Research Station—The Secretary, Research Station (University of Bristol), Long Ashton, Bristol.

**MASTER** (able to teach to university scholarship standard) FOR MATHEMATICS—The Rector, The Edinburgh Academy, Edinburgh, 3.

**MATHEMATICIAN** (qualified to teach to university scholarship level)—The Head Master, Bedford School, Bedford.

**RADCLIFFE-HENRY SKYNNER FELLOW IN ASTRONOMY**—The College Secretary, Balliol College, Oxford.

**SENIOR RESEARCH ASSOCIATE IN INORGANIC CHEMISTRY** to work on reaction mechanisms in boron chemistry under the direction of Dr. J. C. Lockhart—The Registrar, The University, Newcastle upon Tyne.

**TAXONOMIC BOTANIST** (national of the United Kingdom or the Republic of Ireland, with a B.Sc. degree, preferably with some postgraduate practical experience) with the East African Common Services Organization, for duties at the East African Herbarium—The Appointments Officer, Room 301, Ministry of Overseas Development, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/214/02.

# UNICAM SP.800

spectrophotometer for routine  
U.V. analysis and complete  
**automation**

The brilliant new Unicam SP.800 Spectrophotometer is setting new standards in ultraviolet and visible Spectroscopy. The widely acclaimed flat bed presentation, the beam balance smoothing cam and the unique second sample position are among the features which establish it as the outstanding U.V. spectrophotometer. Now, in addition, Unicam offer a set of automation accessories which provide facilities for:

**AUTOMATIC** interchange of up to 4 sample and 4 reference cells

**AUTOMATIC** re-cycling over any preselected wavelength range

**AUTOMATIC** recordings at predetermined time intervals.

*Please send for descriptive brochure*

*Save operator time, increase speed and efficiency with Unicam automation for:*

**ENZYME REACTION RATES**

**LIQUID COLUMN CHROMATOGRAPHY**

**ALL ROUTINE ULTRAVIOLET AND  
VISIBLE SPECTROSCOPY**

**FOR  
PERIODS  
UP TO  
1 hour  
24 hours  
7 days**

**The  
*Histokinette*  
stays on the job**

**Histokinette  
special features  
include :—**

- Up to 24 hours delayed start
- Double processing capacity
- One or more motor members and baskets
- Unbreakable tissue basket and containers

Diagnostic reports to hand hours earlier than they would be with manual processing and in far greater numbers—the release of a valuable technician for other duties... these are the outstanding advantages of the Histokinette Automatic Tissue Processing machine. Once the Histokinette has been put into operation, it will *without supervision* go through the entire cycle of fixation, dehydration, impregnation in wax, or alternatively can be set up for the washing or staining of tissues. It can handle large numbers of specimens at the same time and while staff is off duty—speed up almost any technique by ensuring quicker and more thorough penetration by reagents.

A 24-hour clock is fitted as standard. Change over to 1 hour or 7 day cycles (the latter of great value in double embedding and bone decalcification techniques) is simple and rapid.

## EFFECTIVE NATURE CONSERVATION IN BRITAIN

THE fifteenth annual report of the Nature Conservancy\*, covering the year ended September 30, 1964, like the fourteenth annual report, displays not merely the increasing range of scientific research for which the Conservancy is now responsible, but also the growing extent to which, through its conservation work and also through its scientific advisory service, the Conservancy contributes to the development and utilization of Britain's natural resources. The report, in fact, demonstrates even more clearly how these three sections of the Conservancy's work are related, and for this reason alone the report is of special significance in relation to the proposals which the present Government has formulated for a Ministry of Land and Natural Resources and a Natural Environment Research Council. The Conservancy has always recognized that conservation is too large a task to be undertaken by itself alone, and the present report welcomes the creation of a wider Natural Environment Research Council as the logical outcome of the Conservancy's pioneer work, expressing the hope that the essentially scientific problems arising from the impact of modern man on his natural environment may now be tackled before it is too late.

The Conservancy, however, expressed these views in the light of the statement made to the House of Commons on July 28, 1964, by the Secretary of State for Education and Science, then Mr. Quintin Hogg, regarding the formation of a Natural Environment Research Council with responsibility for the Geological Survey and Museums, the Soil Surveys, the Nature Conservancy, the Hydrology Research Unit and the Committee on Hydrological Research. It would take over, from the Admiralty and the Development Commission, responsibility for the National Institute of Oceanography. It would also establish a Fisheries Advisory Committee and would support research in geophysics, geology, oceanography, fisheries, hydrology, forestry, terrestrial ecology, and Nature conservation as well as research in geomagnetism and seismology, now undertaken by the Meteorological Office. The Nature Conservancy recognizes that years of patient and statesmanlike effort would be required to generate a sense of common purpose and mutual aid among the diverse elements in the life and earth sciences, both terrestrial and aquatic, which were designated for inclusion in the Natural Environment Research Council. That is no less true of the Natural Environment Research Council as proposed by the present Government, which is to take over the functions of the Nature Conservancy and of the National Oceanographic Council and will be responsible for research in the Earth sciences and ecology, including the establishment, maintenance and management of Nature reserves.

What is not yet clear under the new arrangements is where the responsibility lies for conservation—the importance of which is pre-eminent in the Conservancy's present report. The Minister of Land and Natural Resources will now be responsible for the National Parks Commission, for Commons land and the Forestry Commission as well as for the conservation of water, with which the Nature Conservancy has been increasingly

concerned. It is difficult to see how the Conservancy can effectively discharge these duties under the proposed arrangements, and its conservation work is scarcely distinguishable from that required generally for the availability and utilization of natural resources for which the Minister of Land and Natural Resources is now to be responsible.

When the Nature Conservancy writes in the present report that the Natural Resources Research Council would face very real difficulties, it could scarcely have visualized difficulties arising out of such divided responsibilities, nor would it have been so confident that those in charge would pay sufficient attention to the lessons to be learned from past experience to overcome those difficulties and succeed. By and large, it seems that those lessons have been deliberately ignored. It is difficult to share the confidence which led the Conservancy to give full support to the proposal formulated last July and expect a more rapid advance on a much broader front under the new Research Council. On the contrary, unless extreme care is taken in working out the details of the new arrangement, and unless they are administered with vision and clear understanding of the needs of science and conservancy, and those interests are safeguarded with real determination against sectional intrusions, frustration, waste and disappointment are all too probable.

The Conservancy's own anxieties on such matters are reflected in the report without altogether offsetting the confidence with which, at that time, it looked to the future. Once the transitional difficulties were over it hoped that the enlarged teams, setting aside all sectional prejudices, would settle down to their task so that the larger conception, which has now emerged, will prevail. The Conservancy has no illusions about the difficulties and dangers, and it is to be hoped that the Secretary of State for Education and Science, to whom the report is presented, as well as the Minister of Land and Natural Resources, will take due notice of the warning so clearly and reasonably expressed.

The details of the report are summarized on p. 658 of this issue of *Nature*, but there are some general features calling for special comment. First, the Conservancy refers to the initiation by the International Council of Scientific Unions in Vienna in November 1963 of an International Biological Programme. This Programme, which was launched at a General Assembly in Paris in July 1964, is characterized by the Conservancy, which played a leading part in its initiation, as an outstanding event of the year. It brings the support and endorsement of world science to fundamental ecological studies and to the conservation of sites for the use of future scientists—the two principal activities of the Conservancy which it has fostered in Britain on a scale now surpassing anything of the sort elsewhere in the world. Seven sectional committees have now been set up under the Programme and it is expected that during the next two years emphasis will be placed on studying the design and feasibility of projects which will be operated, so far as they prove practicable, during the following five years.

Next, the report refers particularly to important advances made in co-ordinating the efforts and even integrating the policies of the Conservancy, the Forestry

\* Report of the Nature Conservancy for the year ended September 30, 1964. Pp. vii + 173 + 10 plates. (London: H.M.S.O., 1964.) 13s. net.

Commission and the National Parks Commission. The first two of these now manage about 0.5 per cent and 4.5 per cent, respectively, of the total acreage of Great Britain, while a further 9 per cent of the area of England and Wales is included in the National Parks. They both have important research interests, and while the Conservancy and the Parks Commission are free of responsibilities for production they have a special duty of trusteeship for the land from the point of view of amenity and of science. All three are concerned with land and with the impact of human activities on it.

New ways of acting and thinking together have been opened up by meetings between the Chairman and Chief Officers, while liaison with the Agricultural and Education Departments and with numerous semi-official or unofficial interests has also been improved. All this has severely taxed the Conservancy's small staff, but more is still needed in this direction. It remains true that the main threats still come from major Government Departments, such as the Ministry of Power, the Ministry of Transport, the Armed Forces, and the Ministry of Housing and Local Government. It is therefore disconcerting to find that the responsibility for land now rests with a Minister who does not enjoy Cabinet status. Nor is this the only complication, for it is understood that the Parliamentary Secretary to the Ministry of Public Building and Works has a special responsibility for parks and amenities.

The shortage of staff is particularly acute in conservation work, on which, in September 1964, 87 of the Conservancy's staff of 355 were engaged, 44 of these being warden naturalists or wardens. Of the total, 165 are scientifically qualified and carrying out scientific duties. The pressure on conservation work is due in part to the increase in the number of declared national Nature reserves (from 19 to 111 over the past ten years), to the wider application of the system of management under an approved scientific plan, and to the demarcation and recording of sites of special scientific interest. The establishment of the Council for Nature and the county Naturalists' Trusts has also greatly increased conservation activities, though it has sometimes been possible to hand over to the Trusts some non-statutory functions. In consequence, however, of the increasing public and Parliamentary recognition of conservation, Bills coming before Parliament dealing with land-use frequently include specific clauses placing special statutory duties on the Conservancy, as in the case of the Water Resources Act, 1963. The pressures on Britain's remaining natural and semi-natural areas of land and water have greatly increased, and apart from the conflicting claims for natural resources like gravel and peat which are changing the use of the countryside, as already noted, the increase in leisure and wealth, and ease of transport, have made much unspoilt country vulnerable.

The past year has seen a major advance in the general acceptance and application of the outlook, policies and practices of conservation. The inter-relation between the positive management of land and water and the zoning for special uses has been emphasized, notably in the study conference "The Countryside in 1970" and in the Conservancy's co-operative studies on the Broads, Purbeck, Snowdonia and the Cairngorms, which have stressed the importance of enabling Britain's natural resources of land, water and wild-life to sustain their status through suitable management. Pressures are sometimes so intense that new ideas and fresh measures are required to safeguard

the natural resources, including the features of scientific interest, which form part of the national heritage. While in general the conservation and management of a resource have much in common with preservation of amenity, conflict does sometimes arise, and the Conservancy is finding that with so much pressure it is not always easy to maintain the objective approach and cool scientific appraisal of the facts which are essential to the function of a research council.

Already the Conservancy has met the danger by ensuring not only that the regional officers and sufficient supporting staff are well-qualified and experienced in the appropriate sciences, but also that there are close relations between this small number of conservation scientists and the larger number of research workers in the Conservancy's own institutes and in the universities. One outstanding feature of the whole report is the way in which it displays the intimate inter-relation between the conservation work, the scientific advisory services, and the research work which might be regarded as the prime function of a research council. The fear that this delicate, but vital, inter-relation may be disturbed is the prime reason for regarding with misgivings the new situation created by the establishment of a Ministry of Land and Natural Resources separate from the Natural Resources Research Council.

Before leaving this question of conservation, reference should be made to the concern expressed here and in other recent reports over the increasing impact which man is having on his environment and particularly on the countryside. This derives largely from the growth and movement of population, recreation and holiday needs. In coastal areas the competition for land by holiday and outdoor recreational interests constitutes the greatest problem for conservationists, as indeed it does for the National Park authorities. For example, many areas of high scientific interest and special conservation value lie within the undeveloped parts of the East Anglian coastline or in the areas of low-density development. Moreover, at many places, such as Blakeney Point, Winterton Dunes and Minsmere, this increasing public pressure has already led to increasing disturbance to breeding birds, erosion of sand dunes and vandalism. Effective wardening is becoming more difficult and a comprehensive approach to the future use of coastal areas in Britain as a whole is urgently needed.

The Conservancy accordingly notes with approval that the National Trust is to launch a nation-wide coastal campaign to last until December 1966, entitled "Operation Neptune". This is also welcomed by the National Parks Commission in its report (see p. 659 of this issue of *Nature*), which discusses at some length the question of recreational facilities in National Parks and the problem of striking a reasonable balance. It believes with John Dower that while access and facilities for holiday-making should be amply provided, and available to the public at large, National Parks are not the place for those who want to spend their holidays gregariously. The Commission recognizes that in National Parks, in areas of outstanding natural beauty and in the countryside generally, and especially on the coast, some restrictions or prohibitions on motor traffic, the siting of caravans and camping sites, or on the establishment of holiday resorts and of marinas must be accepted. The Conservancy believes that the designation of well-chosen recreation areas and their careful development and management near towns or in the countryside away

from the National Parks might relieve pressure on the Parks.

One reason the Commission desires wider powers is to enable it to discharge such functions better, and the same policy might well assist to relieve pressure on some of the Nature reserves. What is apparent above all is that the problem is one problem for all its wide implications and demand for co-operative effort, and that there must be a single, but adequate, authority to enforce an agreed policy. The hope of the National Parks Commission that in the present Parliament new measures, framed on imaginative and forward-looking lines, to ensure the due protection and proper use of the countryside in the face of mounting demands, will receive high priority in the legislative programme is one that the Nature Conservancy may well endorse.

Two other features of the Conservancy's report call for comment, and both illustrate the close inter-relation of its research work and the scientific advisory services and the importance of close co-operation with other interests. First, the Conservancy returns at some length to the risks to wild-life arising from the use of persistent organochlorine pesticides. The evidence submitted on behalf of the Conservancy to the Advisory Committee on Poisonous Substances used in Agriculture and Food Storage was based on investigations carried out by the Toxic Chemicals and Wild Life Section on organochlorine insecticides residues in wild birds, eggs and mammals and of the peregrine falcon and golden eagle.

The main conclusions of the Conservancy's evidence were that contamination is widespread and is not confined to areas sprayed, freshwater and marine habitats being particularly affected. Birds which feed on vertebrate prey contain higher residues than do insectivores, omnivores and herbivores, and the eggs of predatory birds contain larger amounts of insecticides than do the eggs of other species. The persistent chemicals now in use appear to offer a much more serious threat to wild-life than do less persistent chemicals, both because they build up in natural systems and because they have sub-lethal effects on reproduction. However carefully applied, even at rates well below those likely to cause direct poisoning, they may endanger wild-life. Total contamination of an environment by persistent chemicals from all sources is a factor which must be considered in the control of chemicals. Because their build-up in the field cannot be predicted adequately in the laboratory, persistent chemicals, in the existing state of knowledge, cannot be adequately controlled. The hypothesis that the declines in population and reproductive capacity of the peregrine falcon and of the reproductive capacity of the golden eagle are due to lethal and/or sub-lethal poisoning by organochlorine insecticides is well supported.

Many of the conclusions and recommendations of the Conservancy were accepted by the Advisory Committee, and after publication of the first part of the Committee's report in March 1964, the Minister of Agriculture announced the Government's decision to give full effect to the recommendations and that assurances of co-operation in curtailing the use of these chemicals had been given by all the interests concerned. The Government had also asked the Committee to examine the present voluntary safety measures and to consider whether any improvement or extensions of these would be desirable. Its terms of reference have also been extended to include the use of these organochlorine chemicals for wood preservation and mothproofing. In future, the Committee will primarily be

responsible to the Ministry of Education and Science. The Frazer Committee, which dealt with toxic chemical research, also reported in March 1964, and the report included specific recommendations directing the attention of the Conservancy to the need for further ecological investigations on whole populations of chosen species; for examining the practicability of controlling a land area of about 1,000 acres so as to permit quantitative studies on the effects of pesticides on wild bird populations; and for collaboration with other bodies in investigating contamination of fresh waters by pesticides, their accumulation in animals and the faunal and floral changes in inland waters.

These recommendations are being implemented by the Conservancy "as fully as present resources permit", but it is obvious that all these developments call for greater resources and more staff. That same remark appears in connexion with the pollution of air and fresh water, for although some cases of pollution of rivers and of land from aerial discharges of industrial effluvia affecting the scientific interest were brought to the attention of the Conservancy during the year, these aspects of environmental contamination await further resources before they can be examined fully. The second matter is that of oil pollution of the sea, and while this will remain serious until the recent amendments to the 1954 International Convention for the Prevention of Pollution of the Sea by Oil are accepted and followed by the 24 countries which had ratified the Convention by the end of 1963, the Conservancy's report notes a striking development in this field announced in June 1964.

Shell International Marine, Ltd., and the British Petroleum Tanker Co., Ltd., have devised and tested new techniques which, by obviating the need for ships to clean their tanks at sea, will reduce oil pollution of the sea and beaches considerably. Steps are already being taken to persuade oil carriers throughout the world to adopt this new technique. While it may be several years before oil already floating in the sea becomes wholly dispersed, it is anticipated that the new technique will bring a rapid improvement. Meanwhile, the present report records no large-scale spillages during the year in British waters. However, it is obvious that here, as elsewhere, there can be no relaxation of vigilance, and that the present expenditure of the Conservancy of some £692,000, of which only some £104,000 is allocated to research studentships, training and special surveys, is all too small for the tasks that it is called on to undertake. Together with a fresh look at the appropriateness of the new organization in the light of the facts disclosed in this report, the Ministers concerned might well reconsider the adequacy of the grant-in-aid of no more than £674,000.

## INSECT PHYSIOLOGY

### Advances in Insect Physiology

Vol. 2. Edited by J. W. L. Beament, J. E. Treherne and Sir Vincent Wigglesworth. Pp. xi+364. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1964.) 70s.

VOLUME 2 of *Advances in Insect Physiology* maintains the high standard set by the first volume. Its editors have again drawn heavily on the experience of people who are, or were until recently, members of the Agricultural Research Council Unit of Insect Physiology at Cambridge, but the wide range of subjects covered is evidence of the breadth of interest of this distinguished

group. The articles illustrate well the way in which problems of wide biological interest are now being tackled using insect material, and how necessary it is for anyone who calls himself a general physiologist to be aware of the opportunities offered by animals other than those which are usually found in pre-clinical departments.

Prof. Weis-Fogh leads off with the first full review of the distribution, biochemistry and mechanical properties of the rubber-like protein 'resilin' which he himself discovered only four years ago. This is clearly a progress report, since the researches are being actively pursued in his laboratory in Copenhagen. We may expect soon to hear more about the nature of the covalent links which bind the peptide chains into a three-dimensional framework, and about the way in which the molecular structure is laid down during development.

Dr. Beament has collected together all the evidence, both direct and circumstantial, which has led him to the conviction that active transport of water occurs through various regions of the insect cuticle. The slightly emotional tone of parts of this article can perhaps be understood in view of the difficulties which have attended previous postulations of such a mechanism. Particularly valuable is the discussion of the physico-chemical properties of the polar lipid monolayer which is not in thermodynamic equilibrium with identical solutions on the two sides. This is a good example of the way in which biologists have to be prepared sometimes to re-examine widely held physical principles. The final fourteen pages of this article should be read by everyone interested in the nature and properties of the cell surface.

Dr. Burkhardt discusses colour discrimination in insects and gives a particularly clear account of the misconceptions which can arise when behavioural evidence is used to draw conclusions about physiological mechanisms or *vice versa*. Micro-electrode investigations on single reticular cells, together with training experiments with intact insects, have, however, combined to establish that the hive bee, like man, has a trichromatic visual sense, but shifted 100 m $\mu$  into the ultra-violet. Less is known about other insects.

A major part of Dr. Cottrell's article on ecdysis is biochemical; he includes a full review both of the tanning of the cuticle and also of the nature of the tyrosinases of the blood on the grounds that "it is impossible to know how much of the available information is relevant to sclerotization". It is a pity that the title did not indicate this. Other components of the complex process of shedding and renewing the cuticle are listed and discussed.

Dr. Davey catalogues and discusses the rather inconclusive information which exists about the nature and functions of the visceral nervous system and about endocrine control of the viscera. This is evidently a field of investigation in which much more could be done; it is clear that, though they are striated, the visceral muscles differ in many of their properties from those classed as somatic.

The final chapter by Prof. Wigglesworth on the hormonal control of growth and reproduction brings up to date his earlier surveys. Sixty-nine pages of text and twenty pages of references are needed to cover the work of five years. Although "the subject has reached the point where the comparatively consistent hypotheses which were earlier accepted are being obscured by a multitude of apparent exceptions", this period has seen two of the most important hormones chemically characterized and a beginning made with the understanding of their action on the genetic expression of epidermal and other cells. Further clarification is likely to come, as the author suggests, through experiments which separate "immediate effects" at the cellular level from "the secondary consequences" of hormone action.

The editors' comprehensive author and subject indexes add considerably to the usefulness of the whole book. This ought to be a firm rule for publishers of annual reviews.

J. W. S. PRINGLE

## ADVANCES IN MICROBIOLOGY

### Recent Progress in Microbiology

Symposia held at the eighth International Congress for Microbiology, Montreal 1962. Edited by N. E. Gibbons. Pp. xi + 720. (London: Oxford University Press, 1963.) 172s.

THIS is a well-edited and well-presented account of the eighth International Congress for Microbiology. Papers from thirteen symposia are included and the collection is preceded by the opening addresses of the President of the International Association of Microbiological Societies and the President of the congress. Each symposium opens with its chairman's remarks, some of which serve the useful purpose of giving a broad overall view of the field covered by the symposium.

As might be expected at an international congress, the symposia range over a fascinatingly wide field of interests. In addition, there are reports of three panel discussions on industrial microbiology. The symposia fall under five main headings; the first, "Structure and Function", comprises four papers on membrane permeation and four on the properties of isolated cellular particles. These papers survey important recent advances in molecular biology, even including a paper on "The Biosynthesis of Haemoglobin in Reticulocyte Ribosomes". Many theories are put forward and it is interesting to compare the evidence gained from electron micrography and from biophysical and biochemical techniques. No doubt future symposia will resolve the relative merits of the various theories.

The editor states that "some of the Symposia were planned to cover aspects of Microbiology not covered in recent Congresses for Microbiology", into which category fall the four symposia on agricultural microbiology. Some of the work less familiar to most microbiologists appears in the symposium on insect microbiology under such interesting titles as "Crystalliferous Bacteria", "Entomogenous Fungi" and "The Entomophilic Microsporidians". Two further symposia in this section deal with "Enzymes in Soils" and "Effect of Chemical and Biological Control Measures on Soil Micro-organisms". Some of these papers are a very wholesome reminder to the pure culturists in the ivory towers of their laboratories that we still have a long way to go before we reach a clear understanding of the important and complex problems that abound in the microbial environments of Nature.

It is of interest, too, to read the account of the panel discussion on the "Microbial Production of Amino-Acids". We all realize that one of the great problems of the future will be the provision of food for the world's ever-expanding population, and the harnessing of micro-organisms to the task is a bright possibility. It is cheering to note that a dozen or more amino-acids have been produced by microbial means, in low yield in some cases, but in others the yield is high and in several cases the process competes favourably with the synthetic methods available from organic chemical research. It is to be hoped that further strain selection and a better understanding of genetics will enable the development of high-yielding strains which will provide still cheaper sources of the amino-acids essential to the human diet. All praise to the Japanese workers who have done so much to bring this possibility well on the way to realization.

Supplementary to this theme are the two other discussions covering aspects of the beneficial uses of microbial properties in providing for Man's needs—"Genetics Applied to Industrial Microbiology" and "Evolutionary Operation and Horizons in Industrial Microbiology". There are two symposia on virological topics, one of them on interference and interferon; another deals with the mechanisms of immunity in infectious diseases. Symposia X and XI cover aspects of pleuropneumonia-like organisms as disease agents and the virulence of *Staphylococci*.

Symposium XII once more harries the vexed question of microbial classification, almost entirely from the point of view of bacteria. The serious deficiencies in the present systems of classification as further exposed by the rapid advances in the fields of biochemistry and genetics are once more loudly voiced, but despite the discourses of five eminent scientists who lay bare the problems, there seems little hope that a classification (even of bacteria) satisfactory to all will emerge in the foreseeable future. The final symposium comprises six papers on the "Influence of Environment on the Epidemiology of Mycoses".

The volume is completed by an addendum on the statutes of the International Association of Microbiological Societies; the constituent member societies and the various committees are listed along with a report of the general meeting and plenary session of 1962. At the very end is the resolution on "The Contribution of Microbiology to World Food Supplies", which points only too clearly to the great present need for microbiologists and for work towards this end.

Experimental details are lacking from most of the papers so that they are, on the whole, quite short; any deficiency in this regard is made good by the fact that nearly 2,000 references are listed. One paper, "Mechanisms of Immunity in Virus Infections" by Jonas Salk, lists no references at all—which is a pity. Only three papers appear in French, the rest in English; the *Proceedings* at the end appear in both languages. There has been a break with tradition in omitting the discussions following symposia. It removes a little of the flavour of the book, but it is well justified for reasons of economy, since discussions tend to be reiterative. The table of contents is, thankfully, expanded to include the titles of all the papers and is a model of clarity. The range covered by this volume is quite remarkable and it makes a useful and interesting book for all microbiologists. L. B. QUESNEL

## BRAIN AND BEHAVIOUR OF OCTOPUS

### A Model of the Brain

By Prof. J. Z. Young. (The William Withering Lectures, 1960.) Pp. vii + 348. (Oxford: Clarendon Press; London: Oxford University Press, 1964.) 35s. net.

THE behaviour and neuroanatomy of *Octopus vulgaris* have been intensely investigated during the past fifteen years. This work was originated by Prof. Young and most of the more recent developments have been directly inspired by him. In *A Model of the Brain*, he summarizes the experimental data that have been collected and he reviews the theories of brain functioning to which the data have led. Young's aim has been to discover how the structure of the nervous system of the octopus gives rise to the observed behaviour of the animal: in pursuit of this goal he has made considerable use of the findings and concepts of cybernetics and the investigation of information processing by automata. The book is an outstanding example of what can be achieved when the techniques of classical biology (zoology, neuroanatomy, and neurophysiology) are used in conjunction with the methods of experimental psychology and with concepts derived from the field of automata investigations. It is a foretaste of the results that are likely to be achieved during the next few decades with other species by bringing the different techniques to bear on the same fundamental problem—the relation between brain and behaviour.

There are two reasons why the octopus is a particularly suitable species for this type of investigation. The brain and behaviour are simple enough to be investigated reasonably comprehensively, yet complex enough to be interesting. Whereas the rat brain has of the order of 2,000 different nuclei, the octopus brain has only about

50: the task of tracing out the information flow in the mammalian brain is extremely difficult, but Young has succeeded in getting at least within sight of achieving this with the octopus brain. Secondly, and more prosaically, the octopus is an extremely convenient experimental animal both for lesion work and for behavioural work.

In the early part of the book Young expounds the basic behaviour of the octopus, contrasting this species with other cephalopods and showing how it has adapted to its environmental niche. He then describes the organization of the nervous system, and discusses some of the theories that have been put forward to explain such phenomena as shape recognition in *Octopus*. The most original and important parts of the book, however, are the later chapters in which Young describes the model of learning that he has been developing during the past four years. It is impossible to do justice here to the richness of the ideas presented.

Young argues that there is a hierarchy of centres in the brain originally concerned with giving the reflex commands: "attack food", "draw in food", "bite food", "eat food". The lobes from which the first two commands are issued are much more complex than those issuing the last two. Both attacking food and drawing in food are under the control of distance receptors—respectively vision and touch (the octopus uses its suckers to explore food tactually before drawing it to the mouth). Young shows that there are startling anatomical similarities between the lobes concerned with vision and attack and those concerned with touch and drawing in. Moreover, lesions to corresponding parts of each system have similar effects on the two types of behaviour. Young suggests that in phylogeny the elaboration of these two sets of centres takes place to allow for learning: the animal learns which stimulus objects to attack and which not to attack. Such learning depends on the animal being able to switch the input from a given stimulus to give either an output corresponding to "attack" or an output corresponding to "no attack, or retreat". Such switching must be set up by events that occur after the stimulus has ceased to impinge on the receptors, since the animal is rewarded or punished only after it has attacked and it is this reward or punishment that determines whether the animal will learn to attack or not to attack a given stimulus object. Young argues that some of the elaborations of the lobes concerned, and particularly the recurrent pathways involved, have taken place to enable the animal to keep the representation of the stimulus object "addressed" during the delay between the stimulus occurring and the reward or punishment that follows attacking or drawing in.

In both the lobes concerned with vision and in those concerned with touch there are centres containing a proliferation of small cells: such small cells do not occur in the centres concerned with reflex eating and biting. Young suggests that these small cells may be responsible for setting up the switch involved in learning. Thus, in the cuttlefish, there is no elaboration of the touch system as in the octopus and there is no proliferation of small cells in that system. Presumably, there is little tactual learning in the cuttlefish since it does not use touch as a distance receptor: the lobes concerned with vision are, however, anatomically similar to the corresponding lobes in the octopus.

This account has necessarily oversimplified Young's ideas. Further research will doubtless fill in and complicate many of the details of the model, but the model as it stands gives a very plausible framework within which to understand the basic data on the neuroanatomy and behaviour of the octopus: the construction of such a model at this stage is a very notable achievement.

The book is beautifully written, and conveys the author's own zest for the subject in every line. Although it is mainly devoted to the octopus, it sets the subject in a broad biological perspective, and the story it has to tell

should grip the attention of anyone interested in biological phenomena. *A Model of the Brain* will itself serve as a model of how work on brain functioning should be undertaken and presented for some time to come.

N. S. SUTHERLAND

## AGRICULTURAL RESEARCH

**The Principles and Practice of Agricultural Research**  
By Dr. S. C. Salmon and Dr. A. A. Hanson. Pp. ix + 384.  
(London: Leonard Hill (Books), Ltd., 1964.) 75s. net.

ANY book concerned with the principles and practice of agricultural research is particularly welcome at this time when there is such a need for increased food production in many of the developing countries, and that by Salmon and Hanson is a very good introduction to the subject. Although it does not discuss any particular aspects in sufficient depth to make it a manual for the research worker, it is well-worth reading, not only by agriculturists but also by everyone who is concerned about the world's food supply and methods of increasing it.

The first part gives a brief sketch of the history of agricultural improvements, tracing the development of some of the more important aspects such as plant breeding improvements, and directing attention to the methods used by some of the scientists whose work later became important in agriculture, men such as Liebig, Darwin and Pasteur. This discourse leads to the conclusion that many of the improvements in agriculture have been made without the aid of formal research but that such advances have been painfully slow, indicating that a better understanding of research methods might enable us to proceed more quickly in the future. To this end, the second part is devoted to the 'Philosophy of Research', a very useful section which is pertinent to all research workers, not just those applying their talents to agriculture. The various basic methods of research are discussed briefly and a chapter is devoted to the possible reasons why erroneous conclusions are sometimes drawn. Agriculture, which is so affected by uncontrollable variation, is particularly suitable for directing attention to such difficulties in research and for considering the meaning of 'proof' which the authors discuss in the last chapter of this section.

Part 3 is devoted to statistical methods, a subject which is already very well covered by standard textbooks. This section does not attempt any new explanation but simply shows, mainly by example, how various statistical computations are made, without attempting to show much basic theory. The reader is simply asked to accept that each method is correct; for example, the reason for using standard deviations instead of average deviation "is that many statistical deductions and practically all statistical tables... are based on standard deviations". This approach is no doubt admirable for those who wish to use statistics as a research tool without involving themselves in mathematical formalities, provided they wish to use only those methods detailed in the book; but, if they try to extrapolate the ideas to slightly different designs or situations, lack of fundamental understanding is liable to lead to inefficient experimentation or even erroneous results. However, the impression given of the absolute simplicity of the methods may well encourage those who have been avoiding statistical techniques to examine statistical textbooks and so adopt better designs and analyses. The aspects covered include standard deviation and variance, significance tests using  $t$ ,  $\chi^2$ ,  $F$  and Duncan's multiple-range test, analysis of variance for randomized block designs and other factorial arrangements, Bartlett's test of homogeneity of variance, the use of simple transformations, correlation, regression and co-variance. There is a chapter on sampling which sets out in quite simple terms

the effects of randomization and is a good reminder of the sound views of Fisher which are so often forgotten in these days of more sophisticated statistical techniques. The section ends with a discussion of the uses and limitations of statistical methods which very wisely produces the conclusion that they are no substitute for critical observation and thought, but should be used, where appropriate, for the purposes for which they are designed.

This appreciation of statistics is followed by an examination of the techniques of agricultural research, which first deals with problems found in all kinds of field research, such as differential responses from place to place and year to year, and then goes on to deal with choice of experimental material, size, shape, replication and management of plots in field trials. Another chapter in this section is devoted to experiments with farm animals in which most experimental aspects are mentioned, though none receives very exhaustive consideration, which is to be expected in a book which attempts to cover such a wide subject in so small a space. There is also a chapter on experimental design which demonstrates the possibilities of Latin squares, cross-over trials, split-plot and incomplete plot designs, without attempting to show how these are analysed, and the book ends with some thoughts on the methods of research in agricultural economics including a reference to linear programming.

W. J. RIDGMAN

## MONOSACCHARIDES

### The Monosaccharides

By Jaroslav Staněk, Miloslav Černý, Jan Kocourek and Josef Pačák. Pp. 1006. (New York and London: Academic Press; Prague: Publishing House of the Czechoslovak Academy of Science, 1963.) 228s. 6d.

*The Monosaccharides*, by Jaroslav Staněk, Miloslav Černý, Jan Kocourek and Josef Pačák, is an advanced text and reference work. It was originally published in Czech, but the present volume is an entirely new edition, considerably supplemented and partly rearranged in comparison with the first Czech edition: the literature survey and addenda inserted in the form of notes directly into the text cover the period to mid-1962.

The scope of the volume is so vast that it will best be apparent from its chapters, that deal with: (1) introduction; (2) structure of the monosaccharides; (3) isolation of the monosaccharides from natural material, their properties and industrial utilization; (4) preparation of the monosaccharides by synthetic methods; (5) esters of cyclic monosaccharide forms and organic acids; (6) the glycosyl halides and their derivatives; (7) glycosyl derivatives of aromatic hydrocarbons; (8) esters of monosaccharides and inorganic acids; (9) glycosides and thioglycosides; (10) monosaccharide orthoesters; (11) monosaccharide ethers; (12) condensation products of monosaccharides and carbonyl compounds; (13) sugar anhydrides (glycosans) and anhydro sugars; (14) unsaturated derivatives of monosaccharides; (15) deoxy sugars; (16) glycosylamines; (17) nucleosides; (18) amino sugars; (19) monosaccharide oximes; (20) reaction products of monosaccharides and aromatic hydrazine derivatives; (21) glycosyl azides; (22) oxo derivatives of monosaccharides; (23) the reaction products of monosaccharides and hydrazine, urea, thiourea, guanidine, semicarbazide, thiosemicarbazide and similar compounds; (24) acyclic derivatives of monosaccharides; (25) other derivatives of monosaccharides containing sulphur; (26) alditols; (27) aldonic acids; (28) branched-chain aldonic acids; (29) the saccharinic acids; (30) oxo derivatives of aldonic acids; (31) ascorbic acids; (32) monosaccharide dicarboxylic acids; (33) amino-acids from the monosaccharide series; (34) polyhydroxyalkylbenzimidazoles; (35) inositols and related compounds; (36) synthesis and transformations of sugars in living systems; (37) sugar analysis.

Thus the entire field of monosaccharide chemistry is covered. I thoroughly enjoyed reading the book and was particularly impressed by Chapters 2, 4, 6, 12, 15, 18, 20, 31, 35 and 36. The standard of treatment is uniformly high: reaction mechanisms are given where appropriate and a comprehensive bibliography (including references to the patent literature) is given at the end of each chapter. It is noted that recrystallization of some monosaccharides from boiling solvents may lead to traces of new substances, for example, D-fructose from ethanol.

There can be little doubt that Dr. Staněk's book will be regarded as the standard reference work on the monosaccharides and no carbohydrate chemist can afford to be without it either in his personal library or in his laboratory. I suggest that all libraries should acquire a copy: most organic chemists will wish to own or have access to this excellent book. The price is high, but not unduly so by modern standards having regard to its length and content.

The translation is generally good, but a few isolated clumsy expressions will be found (see, for example, pp. 35, 37, 117, 539): only two misprints were found (pp. 563 and 869). The author and subject indexes are very satisfactory. The book was printed in Czechoslovakia: the production and format are very creditable by any criteria.

A. I. VOGEL

## PEROXIDASE AND RELATED CATALYSTS

### Peroxidase

*The Properties and Uses of a Versatile Enzyme and of some Related Catalysts.* By Dr. B. G. Saunders, Dr. A. G. Holmes-Siedle and Dr. B. P. Stark. Pp. x+271. (London: Butterworth and Co. (Publishers), Ltd., 1964.) 60s.

SINCE the publication in 1948 of Lemberg and Legge's comprehensive *Hematin Compounds and Bile Pigments* no comparable survey of so vast a field has appeared. This is scarcely surprising in view of the explosive growth of knowledge since that time. The present volume, dealing with one group of haemoproteins, is an inevitable development. It provides very broad cover: it deals with sources of enzyme, isolation and purification, chemical and physical properties, spectroscopy and reaction kinetics, possible biological roles, and the chemistry of oxidation products of hydrogen donors in peroxidatic reactions. There is also a chapter on "Contributions to the Problem from Inorganic Chemistry" and an extremely useful atlas of haemoprotein spectra. The sequence of subject-matter does not follow a very logical course: thus a complete account of the Chance mechanism for the reaction of horse-radish peroxidase with peroxides is scattered in four chapters: under general survey, properties of peroxidase, rapid reaction mechanisms and chemistry of peroxide compounds. Other subjects, such as George's concept of higher oxidation states of iron, are similarly fragmented. Although Chapter 8 is entitled "The Spectra and Function of the Haemoproteins", questions of biological function are first considered in Chapter 9. However, a very full index enables such difficulties to be surmounted.

The authors write in two very distinct styles: (1) comprehensive reporting of the literature, devoid of critical evaluation and often highly compressed; (2) authoritative summaries of certain fields to which the authors have themselves made valuable contributions. While it is inevitable that some emphasis of the authors' interests should occur, the imbalance can become excessive as in the introductory chapter "General Survey" in which 28 out of 37 pages are occupied by an account—and an excellent one—of the authors' work on the peroxidation products of phenols and aromatic amines.

The enzyme peroxidase is widely distributed in plants, but many references to animal peroxidases must be

treated with reserve since all haemoproteins, and other haematin derivatives, can catalyse reactions which, at least superficially, are similar to those that characterize peroxidase. However, the activity of such derivatives is lower, by a factor of at least 10,000, than that of the enzyme peroxidase and is at the level of denatured peroxidase. Failure to appreciate this point has been frequent and it is unfortunate that the authors of this book have not driven the point home. They define true, atypical, artificial and model peroxidases and state that, failing indication to the contrary, the term peroxidase will be used to mean true peroxidase, that is, a haemoprotein enzyme. In Chapter 13, however, they make the surprising statement that "most workers agree that true peroxidase activity seems to be largely restricted to iron-porphyrin compounds and to iron phthalocyanines". They then ascribe peroxidase activity to such diverse materials as heavy metal compounds, granite, charcoal, aldehydes, organophosphorus compounds, nucleic acids and vitamin A. Traces of heavy metals can accelerate the peroxidation of typical hydrogen donors for peroxidase, and the list of materials with thermostable peroxidase-like activity can be extended indefinitely (to include even the dust on the laboratory floor) so long as no standard criteria of reaction rates or specific activities are applied.

Chapter 9, on catalase, gives emphasis to the peroxidatic activity of the enzyme. Under "Biological Role" (and again, for no obvious reason, in Chapter 13) are described *in vitro* reactions which the enzyme is known to catalyse. However, we do not know whether such reactions are related to its biological function. A more serious error is the statement, made more than once, that in the functioning of the respiratory chain cytochrome reduces oxygen to hydrogen peroxide and, by inference, that the decomposition of such peroxide is a biological role of catalase. The brief comments (p. 91) on the use of the spectroscope by MacMunn and by Keilin are quite inaccurate and the statement that cytochrome c peroxidase is associated with the respiratory chain will be disputed. Otherwise errors of fact are very few. It is not clear why almost identical tables appear on pages 35 and 147, and the thirteen pages occupied by structural formulae in Appendix A might have been put to better use since most of the formulae appear in Chapter 1.

The authors no doubt felt that considerations of non-enzymatic peroxidation would widen the interest in their book. But to those whose attention is caught by the title, to the enzymologist, these considerations will be seen as intrusions on limited space. While this book contains snares for the newcomer there is no doubt that it will become an essential work of reference for all who wish to keep abreast with developments in haemoprotein catalysis.

E. F. HARTREE

## POSITRONIUM—THE CHEMISTRY OF A MINIAURE HYDROGEN

### Positronium Chemistry

By James Green and John Lee. Pp. xii+105. (New York: Academic Books, Inc.; London: Academic Books, Inc. (London), Ltd., 1964.) 44s.

DESPITE the short history of positronium chemistry and the comparatively few workers actively involved, there is a great amount of recorded data, as is evidenced by the extensive and thorough bibliography provided in this book. The authors have obviously decided to cope with this situation by selecting certain aspects which interest them most. Most readers, however, will require to be 'put in the picture' and this is attempted in an opening chapter of eight pages. This is condensation at its worst and the result is most unsatisfactory. The authors hop

from one aspect of the subject to another without warning and the effect is confusing. In such a situation it is difficult to understand the use of one page of the eight for a largely irrelevant discussion of mesonic atoms.

Chapter 2, "Experimental Methods", is excellent and, together with the references, will be invaluable to any research worker entering the field. The introduction of a sentence on copper-64 into the middle of an account on sodium-22, however, is surprising. So also is the absence of any consideration of the effect of fourteen-stage multipliers on techniques. Two chapters are devoted to interesting summaries of positrons in gases and in solids. A very clear description is given of the behaviour of positrons and positronium in different experimental circumstances and of the various theoretical and experimental investigations up to a very recent date. The effects of electric and magnetic fields, pressure, type of gas or solid are all well described and discussed and make interesting reading.

Chapter 5 deals with the theoretical chemistry of positronium, and the authors from this point onwards are increasingly concerned with positronium as a chemical element. The final two chapters are about positronium chemistry in gases, liquids and solids. It soon becomes apparent that the subject is as yet in a very unsatisfactory state. Experimental results are still unreliable and incomplete. This is perhaps the most useful aspect of this book: it shows clearly where inconsistencies exist, what readings must be repeated and improved, what auxiliary measurements must be made, and where there are serious gaps in the published data. It is manifest that, even when all this is done, interpretation will be difficult, but as things stand interpretation is impossible. Because of the present chaotic state these final chapters make difficult reading—but rewarding reading.

There is much in *Positronium Chemistry* which could be improved. Chapter 1 needs rewriting and expanding considerably, as has been indicated; for the time being, the reader should read one or more of the reviews listed in the introduction. Some re-ordering of material would be helpful. For example, in Chapter 3 (on gases) it is assumed that the reader is familiar with the use of 3 per cent nitric oxide to quench all 3-photon annihilation in gases, which is not explained until Chapter 4 (on solids). In addition there is the usual crop of small confusions and printer's errors. Most of these are trivial, but some are disconcerting. The definition of quenching, for example: "quenching means the conversion in collision of triplet to singlet at a rate much greater than the triplet annihilation..."—surely this should be "at any rate"?  $\tau$ , paralysis time, is used on p. 10 where the resolving time of the coincidence circuit is intended. Most confusing of all, ten lines from the bottom of p. 4,  $n$  factor should be  $N$  factor. Despite these criticisms this is a useful book; it maps positronium country with the uncharted areas clearly shown. It is an important and worth-while addition to the literature.

## THE SCIENCE OF SCIENCE

### The Science of Science

Society in the Technological Age. Edited by Maurice Goldsmith and Alan Mackay. Pp. 235. (London: Souvenir Press, 1964.) 30s. net.

**J.** D. BERNAL'S important book *The Social Function of Science* was published in 1939. It had considerable influence and many of its conclusions are now part of the assumptions of everyday life of those who have any broad social awareness. Its principal theme was that science could, and should, be planned and that this planning was susceptible to rational analysis. The work now under review, twenty-five years after the publication

of the former book, offers a perceptive assessment of the present position with regard to the social uses of science.

A considerable number of Bernal's recommendations and prophecies have become fact. The contributors include some of the foremost names in science to-day: Blackett, Haldane, Kapitsa, Needham, Powell, de Solla Price, Sir Charles Snow and Synge—three Nobel prize winners, nine Fellows of the Royal Society. They develop Bernal's view that an affluent, prosperous, developing society free from war, hunger, unemployment and tyranny is possible. The book is also intended to do public honour to Prof. Bernal and commences with a spirited biographical account of him by Sir Charles Snow.

The royalties from the sale of *The Science of Science* are to be used to help set up a Science of Science Foundation, the object of which will be to promote the application of scientific methods to the understanding of science itself, especially in its relations with society (see *Nature*, 205, 10; 1965).

Each of the chapters, written by a scientist of distinction, could have been expanded without superfluity to a large book. The whole publication is a masterpiece of compression. It is packed with good topics for critical and creative discussion in sixth-form, university and extra-mural classes. Not only science teachers but those who have at heart the condition of Man and his future, anywhere in the world, should know the problems with which it deals. If prospective Members of Parliament ever have to pass an elementary examination before being elected, this should be one of the half-dozen set books.

To some of the chapters there is appended a bibliography or reading list. This might have been extended to all of them. Other chapters of equal interest include a version of Blackett's 1957 address to the British Association for the Advancement of Science; Herbert Coblan's chapter on the problems of scientific communication, in particular, those of the enormous bulk and number of new scientific papers every year; Kapitsa on future problems of science; Needham on eastern and western science; Haldane on human genetics; Pirie on the maldistribution of research effort; Korach on the science of industry; Price on the science of science; and Bernal's own reflexions on the applications of science in the past quarter of a century.

Naturally, the political ideas of some of the writers do not show the same objectivity as those of their scientific statements, but the discerning reader can consider them in conjunction with one another. Thus we have "One must admit some truth to the platitude that the scientist outside his chosen discipline reverts to the status of layman" (Price) and "At your schools they taught you the laws of Newton—but why did they not teach you Marx's sociological laws in the capitalist countries? Indeed, there are laws on society which are valid for the whole globe, wherever society exists, they are as valid in all human societies, just as the law of attraction—Newton's discoveries are valid for any body" (Kapitsa). Nevertheless, capitalism, or individual effort, does not seem, by implication, to be so bankrupt: "In addition to likely commercial and government short-term lending, an additional £1,000 million a year is needed as a free gift or as long-term loans from the 400 million rich Westerners to the 1,000 million Asians, Africans and South Americans in the underdeveloped countries outside the society orbit" (Blackett), and "Over the past decade one of the principal measures for sustaining U.S. agricultural economy against the crushing burden of its surpluses has consisted in shipping those surpluses overseas to feed the hungry. Since 1954 more than Dollar 9,000 million worth, 75 million tons of agricultural commodities have been delivered to forty-four developing countries. Shipments of wheat alone have amounted to two entire bumper crops. India has been the principal recipient of these shipments, more than Dollar 2,000 million worth" (Piel).

**Imperfections and Active Centres in Semiconductors**

By R. G. Rhodes. (International Series of Monographs on Semiconductors, Vol. 6.) Pp. xii+373. (London and New York: Pergamon Press, 1964.) 90s. net.

**A**LTHOUGH the word "semiconductors" is used in the title, this book is in reality a review of certain properties of germanium and silicon, and mention of other materials is extremely brief. The topics covered are the detection, geometry and motion of dislocations including plastic deformation and twinning, crystal growing and the behaviour of impurities incorporated during growth and by diffusion techniques. A final chapter deals with the chemistry of etching of germanium and silicon and a discussion of the formation of etch pits produced by defects. The general theme is the interactions between various defects including dislocations, vacancies and impurities and the effects of such reactions on the electrical properties of the bulk material; there is no discussion of such effects in thin films prepared by vapour phase growth.

R. G. Rhodes states that the book should be useful in teaching, as well as of practical help to the specialist, and for this reason brief elementary discussions are given as introductions to some of the chapters. The teaching value, however, appears to be rather limited, since the main subject-matter is quite definitely specialized. The space devoted to the elementary preambles which are covered more generally and in more detail in other texts could have been used to amplify other sections which are treated in only a cursory manner. For example, although considerable space is devoted to the detection of dislocations by X-ray methods, the technique of electron microscopy is dealt with in one page; the wealth of information on the behaviour of impurities and their interactions with one another and defects, such as vacancies as determined by electron spin resonance, is scarcely mentioned. In addition there is virtually no mathematical formulation of the various elastic interactions and kinetics of diffusion and precipitation which are discussed.

*Imperfections and Active Centres in Semiconductors* is, therefore, rather disappointing because of its incompleteness. It should, however, be of value to technologists and new research workers entering this field, since it gives a factual survey of the literature up to and including 1962 with adequate references apart from the deficiencies noted here.

R. C. NEWMAN

**Trace Analysis of Semiconductor Materials**

Edited by J. Paul Cali. (International Series of Monographs on Analytical Chemistry, Vol. 11.) Pp. ix+282. (Oxford, London, New York and Paris: Pergamon Press, 1964.) 70s.

**T**RACE analysis of semiconductor materials presents problems of exceptional severity because of the extremely low levels at which impurities can have a significant effect on the properties of these materials. *Trace Analysis of Semiconductor Materials* aims to give an account, up to 1961, of the battle being fought by the semiconductor analyst to achieve the necessary sensitivities.

The book essentially consists of four chapters, each by specialist authors. The first, and perhaps appropriately the longest, chapter is on activation analysis, by J. P. Cali. A short second chapter, by P. E. Lightly and E. W. Currier, is concerned with emission spectroscopy, and Chapter 3, by R. E. Honig, deals with mass spectrometry. Chapter 4, by C. A. Parker and W. T. Rees, comprises three sections on absorptiometric, fluorimetric and polarographic methods.

The book therefore in effect consists of a series of monographs on the six particular analytical techniques which have been found most rewarding in semiconductor trace analysis. It is perhaps a pity that the coverage was not extended to consider a number of matters common

to the various techniques of trace analysis, for example, the vexed problem of sample preparation, and the difficulties of preparing ultra-pure reagents to permit the analysis of ultra-pure materials. On the other hand, there is much to commend. The emphasis throughout is on information of practical value; in particular the radiochemical separations and the table of published analyses in Chapter 1, and the analytical methods detailed in Chapter 4, are most useful compilations. The book could also be of value to many analysts not concerned with semiconductor materials.

H. J. CLULEY

**Genetics of Forest Tree Improvement**

By J. W. Wright. Pp. xvi+399. (Rome: Food and Agriculture Organization of the United Nations; London: H.M.S.O., 1964.) 20s.; 4 dollars.

**I**T is some two hundred years since Duhamel du Monceau published his observations on hereditary behaviour in forest trees, and although later workers have interested themselves in freak forms of trees, in hybrids and in provenance trials, no serious attempt was made to bring about improvement in forest trees until the present century. In fact, credit must be given to the Americans for first adopting "Tree Breeding" in the name of a forest research station. This was in 1925. Many developments have taken place since then and the silviculturist realizes the useful tool he has in the subject of forest genetics. The recent publication, *Genetics of Forest Tree Improvement*, prepared by J. W. Wright and issued by the Food and Agriculture Organization of the United Nations, deals with the subject in a most comprehensive way. It is said in the foreword that the book is aimed at three types of readers—experienced professional tree breeders, students and practising foresters. There is no doubt that these aims have been achieved in the subject-matter and its lay-out.

For obvious reasons much of the genetic improvement work must be expected in species which are commonly planted rather than in those in which natural reproduction is the rule. The rate of improvement is usually more spectacular in species planted outside their natural range, such as *Pinus sylvestris* in the United States, *P. radiata* in the southern hemisphere and eucalypts in the Mediterranean countries. But genetic gains are also being demonstrated in species which are planted within their native ranges, such as Douglas fir in the Pacific north-west. All this is a very different story from what has happened when trees have been raised from unknown provenances and planted in the wrong sites. The result has been a waste of time and money.

After giving illustrations of basic genetic principles, the author deals with population genetics, pollen migration rates, tree selection and selective tree breeding. There are general remarks on geographic variation in forest trees and examples are quoted for a number of species. The professional breeder will find much interest in the chapter on species and racial hybridization. The importance of exotic trees for afforestation and reafforestation schemes is well known and the author claims that species introduction is best considered as a part of forest genetics because differences between species and ecotypes are a matter of degree and therefore tests of new species and new ecotypes should be organized as part of a tree-breeding programme. He adds that the present generation of foresters is largely dependent on tree breeders for most of their detailed knowledge of exotics. There are also fascinating chapters on polyploidy, experimental design and analysis, controlled pollination and vegetative propagation. Finally, there is a most useful, and essential, glossary.

Much more could be said about this book, but it can be summed up by saying that it is ably presented and is a very valuable contribution to forestry literature.

C. J. TAYLOR

## HYBRID CELLS DERIVED FROM MOUSE AND MAN: ARTIFICIAL HETEROKARYONS OF MAMMALIAN CELLS FROM DIFFERENT SPECIES

By PROF. HENRY HARRIS and DR. J. F. WATKINS

Sir William Dunn School of Pathology, University of Oxford

THE ability of certain animal viruses to induce the formation of multinucleate cells by fusing together single cells suggested the possibility that these viruses might be used to amalgamate different cell types and thus produce artificial animal cell heterokaryons. In this article we describe some properties of heterokaryons which we have produced by fusing together cells of human and murine origin.

The two cell types used in the present experiments were HeLa cells (originally derived from a human carcinoma) and mouse Ehrlich ascites tumour cells. These cells were chosen because they could be obtained in quantity as suspensions of single cells: the HeLa cells were grown *in vitro* in suspension culture<sup>1</sup>; the Ehrlich tumour was maintained in the ascitic form in the peritoneal cavity of Swiss mice. Some experiments we have made with other cell types indicate, however, that the technique can be applied to a variety of cells, including differentiated somatic cells, provided that they are susceptible to the strain of virus used to produce fusion. Of the large number of viruses which are known to induce the formation of multinucleate cells, the para-influenza I group of myxoviruses seemed the most promising, because it had been shown by Okada<sup>2</sup> that one strain of these viruses (H<sub>1</sub>VJ) could induce rapid fusion in suspensions of Ehrlich ascites cells *in vitro*. The virus used in the present experiments was a strain of Sendai virus supplied by Dr. H. G. Pereira of the National Institute for Medical Research, Mill Hill.

The virus was propagated in the following way. Infected allantoic fluid with a titre of 8,000 haemagglutinating units/ml. was diluted 1 in 10<sup>4</sup> with phosphate-buffered saline: 0.1 ml. of this preparation was injected into the allantoic cavity of 10- or 11-day-old fertile hens' eggs, which were incubated for 3 days at 37° C. The eggs were then maintained at 4° C overnight and the allantoic fluid collected. The pooled allantoic fluid was centrifuged at 400g for 10 min and the haemagglutination titre of the supernatant determined. The supernatant was then centrifuged at 30,000g for 30 min and the deposit resuspended in one-tenth of the original volume in Hanks's solution<sup>3</sup> (used throughout the present experiments without glucose). The haemagglutination titre was again determined and the concentrated virus suspension stored in 1-ml. lots at -70° C. This suspension, suitably diluted in Hanks's solution, was used for the experiments. Haemagglutination titrations were performed in Salk-pattern haemagglutination trays. Doubling dilutions of virus were made in 0.5 ml. of phosphate-buffered saline, and approximately 2.5 × 10<sup>7</sup> guinea-pig erythrocytes suspended in 0.05 ml. of this saline were added to each cup. The smallest amount of virus which produced complete haemagglutination after 2 h at room temperature was defined as one haemagglutination unit (HAU).

Since any investigation of the physiology of the heterokaryons would be greatly complicated if these cells were engaged in virus production, the virus used to produce cell fusion was inactivated by ultra-violet light. One ml. of the concentrated suspension of virus in a watch-glass was exposed for 3 min to ultra-violet light emanating from a Philips 15-W 18-in. germicidal tube, type 'T.U.V.'. The intensity of the radiation incident on the surface of the fluid was 3,000 ergs/cm<sup>2</sup>/sec. The suspension of virus was mixed by pipetting at the end of the first and second

minutes. Infectivity titrations on the irradiated virus were carried out by a modification of Fulton's method<sup>4</sup> in which pieces of chorio-allantoic membrane were incubated with the virus in Medium 199 (ref. 5) in a haemagglutination tray. It was found that after 3-min exposure to ultra-violet light under the present conditions, the infectivity of the virus, as measured by the production of haemagglutinin, was reduced to levels at which the measurements were obscured by the haemagglutination produced by the initial viral inoculum. This represented a reduction in infectivity of at least 3 logs. Although the ability of the virus to multiply in the chorio-allantoic membrane had thus been drastically reduced, its ability to induce cell fusion *in vitro* remained unimpaired. Evidence will be presented to show that the virus inactivated by ultra-violet light was not reactivated in the vast majority of the heterokaryons.

The technique used for inducing cell fusion was essentially similar to that described by Okada<sup>2</sup>. HeLa cells from a suspension culture were spun down and resuspended at a concentration of 2 × 10<sup>7</sup> cells/ml. in Hanks's solution. Ehrlich ascites cells, withdrawn from the peritoneal cavity, were washed once by centrifugation in this solution and then resuspended in it at a concentration of 2 × 10<sup>7</sup> cells/ml.: 0.5 ml. of each cell suspension was pipetted into a chilled inverted T-tube together with 1.0 ml. of the suspension of virus, diluted, if necessary, in Hanks's solution. The cells clumped immediately, and the size of the clumps was roughly proportional to the amount of virus added. The T-tube was kept at 4° C for 15 min and then shaken in a water bath at 37° C for 20 min at a rate of 100 excursions/min. During this time the cells in the clumps underwent varying degrees of fusion. Fig. 1 shows an electron micrograph of a section through a pellet of cells obtained by centrifuging a preparation at 200g for 10 min immediately after the period of shaking at 37° C. A trinucleate cell is shown, formed by the fusion of three discrete cells; and a fourth cell is seen in the process of fusing with this trinucleate cell.

One ml. of the cell suspension and 5 ml. of culture medium were pipetted into a 6-cm-diameter Petri dish containing 15 coverslips 1 cm in diameter. The culture medium consisted of 20 per cent calf serum and 1 per cent tryptose broth in Medium 199, to which penicillin at a concentration of 100 international units/ml. and streptomycin at a concentration of 100 µg/ml. were added. The dishes were incubated at 37° C in a gas mixture of 5 per cent carbon dioxide in air. The coverslips were transferred to fresh medium after 24 h and again after 4 days.

Four h after the cell suspension had been introduced into the Petri dishes multinucleate cells were found to have adhered to the coverslips; and within 24 h most of these had flattened out on the glass. From cell counts it could be calculated that the multinucleate cells adherent to the coverslips accounted for about 10 per cent of the single cells originally present in the suspension. Each of these multinucleate cells contained from 2 to about 20 nuclei. The nuclei were of two easily distinguishable morphological types. With May-Grünwald-Giemsa or Leishman stain one type of nucleus stained more deeply than the other. The more deeply staining nucleus contained numerous small nucleoli or coarse condensations of chromatin, while the less deeply staining nucleus con-

Fig. 1. An electron micrograph of a section through a preparation in which HeLa cells and Ehrlich ascites cells were fused together. A trinucleate cell is shown, formed by the fusion of three discrete cells. A fourth cell, on the right, is seen in the process of fusion with the trinucleate cell. (By courtesy of Dr. G. I. Schoeff)

tained one to three large nucleoli. The two types of nucleus are illustrated in Fig. 2, which shows a tetranucleate cell containing two nuclei of each type. Since the deeply staining pachychromatic nuclei clearly resembled the nuclei of Ehrlich ascites cells, and the less deeply staining nuclei resembled the nuclei of HeLa cells, it was difficult to avoid the conclusion that the multinucleate cells were formed by fusion of the two cell types. This was confirmed in the following way: 100  $\mu$ c. of tritiated thymidine was added to a suspension culture of HeLa cells at 10 a.m., 2 p.m., 6 p.m. and 10 p.m. on one day, and again at 7 a.m. and 10 a.m. on the following day. Since the generation time of the cells under these conditions was about 20 h, it was thought that this procedure would succeed in labelling the nuclei of virtually all the cells in the culture. Autoradiographs of smears of the cells, made 2 h after the final addition of tritiated thymidine, confirmed that this was so. When a mixture of labelled HeLa cells and unlabelled Ehrlich ascites cells was treated with virus, autoradiographs of the resulting multinucleate cells revealed that the deeply staining pachychromatic nuclei were not labelled, whereas the less deeply staining nuclei with the large nucleoli were. This is illustrated in Figs. 3-5, which show a series of heterokaryons containing labelled and unlabelled nuclei in varying proportions. When the reciprocal experiment was made with labelled Ehrlich ascites cells and

unlabelled HeLa cells, it was found that the deeply staining pachychromatic nuclei were labelled and the others were not. It is thus clear that the multinucleate cells were indeed formed by the fusion of HeLa cells with Ehrlich ascites cells. At least 98 per cent of the multinucleate cells were heterokaryons when virus concentrations of 8,000 HAU/ml. or more were used to induce the cell fusion (Table 1).

Table 1. EFFECT OF VIRUS CONCENTRATION ON THE CHARACTER OF THE HETEROKARYONS PRODUCED

Counts made 24 h after formation of heterokaryons	Concentration of virus used			
	Virus inactivated by ultra-violet light	800 HAU	8,000 HAU	Infective virus 8,000 HAU
Percentage of multinucleate cells which were heterokaryons	77	99	98	97
	84	98	97	99
	85	97	97	99
Mean	82	98	98	98
No. of nuclei per heterokaryon	4.0	(18.4)	10.0	6.3
	4.3	5.9	8.5	5.1
	4.4	9.4		7.4
Mean	4.2	(11.2)	9.3	6.3
Ratio of HeLa nuclei to Ehrlich ascites nuclei	2.8	1.9	3.2	2.3
	1.9	2.1	2.7	2.6
	2.5	2.0		2.6
Mean	2.4	2.0	3.0	2.5
Ratio of multinucleate to mononucleate cells	1.0	3.5	8.4	3.1
	0.6	2.0	7.5	9.0
	0.8	3.1		8.4
Mean	0.8	2.9	8.0	6.8

The average number of nuclei per heterokaryon and the ratio of multinucleate to mononucleate cells could be varied by changing the concentration of virus used. Table 1 shows that at lower concentrations of virus the number of nuclei per heterokaryon and the ratio of multinucleate to mononucleate cells fell. Since the proportion of the original cell suspension recovered as multinucleate cells was unaffected by the concentration of virus used (Table 2), the increase in the ratio of multinucleate to mononucleate cells at higher concentrations of virus must have resulted from preferential elimination of mononucleate cells. This was apparently due to the fact that the multinucleate cells were more resistant to the cytotoxic effects of the virus than the mononucleate cells, a conclusion supported by the observation that infective virus eliminated a greater proportion of the mononucleate cells than inactivated virus at the same concentration (Table 1). With high concentrations of virus, however, and especially with infective virus, some of the multinucleate cells showed marked vacuolation. Table 1 also shows that the ratio of HeLa nuclei to Ehrlich ascites nuclei in the heterokaryons was between 2 and 3 irrespective of virus concentration. This preponderance of HeLa nuclei might be due either to the fact that HeLa cells fuse more easily than Ehrlich ascites cells or, more probably, to the fact that cells with

surfaces containing a large HeLa contribution adhere more readily to glass. Ehrlich ascites cells adhere poorly to glass, so that heterokaryons containing a preponderance of Ehrlich ascites components might also adhere poorly. In this way, adhesion to glass might select heterokaryons with predominantly HeLa surface characteristics.

While they remained multinucleate the heterokaryons did not multiply, but, under suitable conditions, they remained alive on the coverslips for at least five days. After this time some of them began to degenerate and to lose their attachment to the glass, but others survived for

Fig. 3. Autoradiograph of a binucleate cell containing one HeLa nucleus and one Ehrlich ascites nucleus. The HeLa cells had been grown in tritiated thymidine before the heterokaryons were produced. The HeLa nucleus is labelled and the Ehrlich ascites nucleus is not. ( $\times 1,300$ )

Fig. 4. A tetranucleate cell from the same population as the cell shown in Fig. 3. Three labelled HeLa nuclei and one unlabelled Ehrlich ascites nucleus are shown. ( $\times 1,300$ )

Fig. 5. An octonucleate cell from the same population as the cells shown in Figs. 3 and 4. Six labelled HeLa nuclei and two unlabelled Ehrlich ascites nuclei are shown. ( $\times 1,300$ )

as long as 15 days. Time-lapse cinemicrography revealed that some of the multinucleate cells exhibited sluggish locomotion: they moved a distance approximately equal to their own length in 4 days. The survival times of the heterokaryons produced with different concentrations of inactivated virus and with infective virus are shown in Table 2. The essential reason for the failure of the heterokaryons to multiply appeared to be the fact that the cells contained more than one nucleus. Multinucleate cells containing only HeLa nuclei also failed to multiply, thus indicating that it was the multinucleate state rather than heterokaryosis which was responsible for the deficiency. In mixed cultures containing both mononucleate and multinucleate cells, the mononucleate cells did multiply. It was therefore unlikely that failure of multiplication was due to the injury produced by the virus.

Since each heterokaryon received a large number of virus particles, the possibility existed that the virus inactivated by ultra-violet light might undergo multiplicity reactivation. In order to examine this possibility the production of infective virus and haemadsorption<sup>6</sup> were investigated. For haemadsorption studies two coverslips were examined each day. They were washed once in Hanks's solution and placed in the cups of a haemagglutination tray: 0.5 ml. of a 3 per cent (v/v) suspension of guinea-pig erythrocytes in Medium 199 was added to each cup and the tray was left at room temperature for 2 h, during which time the erythrocytes settled evenly over the coverslips. These were then removed, washed four times in Hanks's solution, fixed in methanol and stained with May-Grünwald-Giemsa. The percentage of heterokaryons showing adsorption of one or more erythrocytes was then determined. The results are summarized in Fig. 6. This shows that when infective virus was used to make the heterokaryons, all of them exhibited the presence of surface haemagglutinin for at least 5 days. But when the heterokaryons were made with inactivated virus, surface haemagglutinin disappeared from the cells at a rate which depended on the initial virus concentration. Moreover, with infective virus, the haemadsorption was massive and involved the whole of the cell surface; with inactivated virus, haemadsorption, in the decreasing number of cells which showed it, involved a progressively smaller part of the individual cell surface. At the lowest concentration of virus (800 HAU/ml.) less than 0.05 per cent of the heterokaryons exhibited haemadsorption at 24 h. On subsequent days occasional heterokaryons (between 0.5 and 1 per cent) did show haemadsorption, but it is clear that at least 99 per cent of the cells did not produce any viral haemagglutinin during the 5-day period. The

Fig. 6. Rate of loss of surface haemagglutinin in heterokaryons produced by infective virus and virus inactivated by ultra-violet light. A, Infective virus at a concentration of 8,000 HAU/ml. B, C, D, Inactivated virus at concentrations of 80,000, 8,000 and 800 HAU/ml., respectively.

loss of haemagglutinin from the surface of the heterokaryons produced by inactivated virus no doubt reflects the gradual destruction or elution of the initial inoculum.

In order to examine whether heterokaryons produced by inactivated virus released any infectious virus into the medium, 10 coverslips bearing such heterokaryons were transferred to fresh medium after 24-h cultivation and were then incubated in this medium for a further 48 h. At the end of this period 10-fold dilutions of the medium were made in Hanks's solution and 0.1 ml. of each dilution inoculated into the allantoic cavity of two 10- or 11-day-old fertile hens' eggs. After incubation for 48 h at 37°C the allantoic fluids were collected and their haemagglutinin content titrated. The results of this experiment are set out in Table 3, in which the calculated amount of infectious virus produced per heterokaryon is shown. One unit of infectious virus is defined as the amount which produced 2 HAU/ml. of allantoic fluid in 48 h. It will be seen that, when the heterokaryons were made with inactivated virus at a concentration of 800 or 8,000 HAU/ml., less than one heterokaryon in a thousand produced a single unit of infectious virus. With 80,000 HAU of inactivated virus a yield of 1-10 units of infectious virus per heterokaryon was obtained. This does not, however, necessarily mean that multiplicity reactivation had occurred. Small amounts of virus probably escaped inactivation by ultra-violet light, and these might have been responsible for the yield of infectious virus. When the heterokaryons were made with 8,000 HAU/ml. of virus which had not been inactivated, the yield of infectious virus was also only 1-10 units per heterokaryon. This suggests either that auto-interference had occurred or that the virus, even when it is not inactivated, grows poorly in this system. It is, in any event, clear that with moderate or low doses of inactivated virus at least 99 per cent of the heterokaryons produce neither infectious virus nor viral haemagglutinin.

The usefulness of heterokaryons for the analysis of nucleo-cytoplasmic relationships depends to a large extent on the ability of the two sets of nuclei to synthesize RNA

and on the ability of the hybrid cell to synthesize protein. These two functions were therefore examined by studying the incorporation of tritiated uridine into RNA and tritiated leucine into protein. Heterokaryons, which had been maintained on coverslips for periods up to 5 days, were incubated for 2-6 h with tritiated uridine. The cells were then fixed, digested for 30 min at 37°C with deoxyribonuclease and extracted with 0.3 N trichloroacetic acid at 4°C. Autoradiographs of such preparations revealed that all the nuclei in the heterokaryons were labelled. The cytoplasm became labelled also, but more slowly than the nuclei, as in other nucleated cells. Fig. 7 shows an autoradiograph of a heterokaryon from a 24-h culture exposed for 2 h to tritiated uridine. The cell contains a HeLa nucleus and an Ehrlich ascites nucleus: both are labelled, and there is also slight labelling over the cytoplasm. Fig. 8 shows a similar heterokaryon exposed for 6 h to tritiated uridine: the cytoplasm of the cell is now heavily labelled. There was no marked disparity between the HeLa nuclei and the Ehrlich ascites nuclei in their ability to incorporate tritiated uridine into RNA, or, during the first 5 days, between the amount of nuclear labelling in the heterokaryons and the amount in neighbouring mononucleate cells. It thus appears that synthesis of RNA takes place in the heterokaryons in a manner comparable with that seen in mononucleate cells, and that both sets of nuclei

are involved in this synthesis. The genes of both mouse and man are therefore transcribed.

Autoradiographs of heterokaryons, maintained on coverslips for periods up to 5 days and then exposed for 6 h to tritiated leucine, revealed generalized labelling over nuclei and cytoplasm (Fig. 9). Failure to extract this label with 0.3 N trichloroacetic acid at 90°C confirmed that the tritiated leucine had been incorporated into protein. It is therefore clear that the heterokaryons synthesize protein as well as RNA.

Although heterokaryons in the multinucleate state did not multiply, they did synthesize DNA. When cultures which had been maintained on coverslips for 24 h were exposed for 2 h to tritiated thymidine, autoradiographs showed that about 70 per cent of the heterokaryons contained labelled nuclei. In 5 per cent of these labelled heterokaryons all the nuclei in the cell incorporated the precursor, but in the rest labelled and unlabelled nuclei were present in varying proportions. In any one cell some nuclei of each type might be labelled and others not. Fig. 10 shows a multinucleate cell in which all the nuclei are synthesizing DNA, and Fig. 11 shows a multinucleate cell in which only two of the Ehrlich ascites nuclei are synthesizing DNA. In these labelled heterokaryons about 80 per cent of the Ehrlich ascites nuclei were synthesizing DNA, but only about 30 per cent of the HeLa nuclei. The percentage of heterokaryons showing labelling after 2 h exposure to tritiated thymidine fell from 70 at 24 h to 55 at 48 h, 44 at 4 days and 31 at 7 days. But in those heterokaryons which did show some form of nuclear labelling, the proportion of Ehrlich ascites nuclei and of HeLa nuclei which were synthesizing DNA underwent little change over 7 days. An exponentially growing population of Ehrlich ascites or HeLa cells exposed to tritiated thymidine for 2 h would show labelling in about a third of the nuclei, an expression of the duration of

the phase of DNA synthesis relative to the total intermitotic time. The very high proportion of labelled Ehrlich ascites nuclei in the heterokaryons, therefore, means that these nuclei have become partially synchronized in the phase of DNA synthesis. This partial synchronization might have resulted from selection during cell fusion of those Ehrlich ascites cells in which synthesis of DNA was taking place. But the fact that 80 per cent or so of the Ehrlich ascites nuclei in labelled heterokaryons were synthesizing DNA not only at 24 h, when 70 per cent of the heterokaryons were labelled, but also at 48 h, when 55 per cent of the heterokaryons were labelled, suggests another explanation. It seems more probable that many of the Ehrlich ascites nuclei which were not in the phase of DNA synthesis at the time of formation of the heterokaryons passed into this phase during the first 24 h, and that DNA synthesis was not terminated abruptly after a few hours, as occurs in normal cells, but continued for much longer periods. Any alternative explanation would seem to require that at least some of these nuclei underwent two or more normal cycles of DNA synthesis without mitosis. Why the percentage of HeLa nuclei synthesizing DNA at 24 h should be so much lower is obscure, but, since this percentage also shows little change on subsequent days, it is likely that the phase of DNA synthesis was prolonged in at least some of the HeLa nuclei also. These findings, in any event, make one point clear. Whether or not a mammalian cell nucleus synthesizes DNA cannot be solely determined by events in the cytoplasm. Even in a common cytoplasm DNA synthesis may, at any one time, be taking place in some nuclei and not in others; and the

Fig. 10. Autoradiograph of a heterokaryon from a 24-h culture exposed for 2 h to tritiated thymidine. All the nuclei are synthesizing DNA. ( $\times 1,100$ )

Fig. 12. A cell containing a giant nucleus produced by fusion of a number of discrete nuclei. Several nucleoli or condensations of chromatin are to be seen. ( $\times 1,100$ )

Fig. 13. A heterokaryon in which two of the Ehrlich ascites nuclei are in the process of fusion. ( $\times 1,100$ )

had been grown in tritiated thymidine with unlabelled Ehrlich ascites cells, and vice versa. Autoradiographs of such preparations showed that many of the large nuclei were labelled over only one part of the nucleus. Fig. 13 shows a heterokaryon in which two of the Ehrlich ascites nuclei are in the process of fusion. Fig. 14 shows a giant nucleus in a preparation made by fusing labelled Ehrlich ascites cells with unlabelled HeLa cells: only the right-hand half of the nucleus is labelled.

It might be thought that nuclear fusion represented an extension of the activity of the virus to the nuclear membrane. But experiments on the relationship between the concentration of virus used and the amount and rate of nuclear fusion revealed that this was not the case. Fig. 15 demonstrates that the percentage of cells showing nuclear fusion on successive days is inversely related to the concentration of virus used. With inactivated virus at a concentration of 800 HAU/ml., about 25 per cent of the heterokaryons showed some degree of nuclear fusion at 24 h, and by 5 days nuclear fusion had occurred in almost all the cells. But Fig. 6 demonstrates that at least 99 per cent of the heterokaryons produced by this concentration of inactivated virus had lost all trace of virus haemagglutinin from their surface within 24 h. It therefore appeared unlikely that nuclear fusion, which progressed throughout

Fig. 14. Autoradiograph of a large nucleus produced by fusion of labelled Ehrlich ascites nuclei with unlabelled HeLa nuclei. The Ehrlich ascites cells were exposed to tritiated thymidine before the heterokaryons were produced. Only the right-hand half of the nucleus is labelled. ( $\times 1,300$ )

nuclei from one species may be more active in the heterokaryon than the nuclei from another. The ability of the nucleus to synthesize DNA must therefore depend, at least in part, on factors operating within the nucleus.

Over a 7-day period there was a progressive fall not only in the proportion of heterokaryons showing labelling after exposure to tritiated thymidine, but also in the intensity of the labelling. At 24 h there was no great difference between the intensity of nuclear labelling in the heterokaryons and that found in neighbouring mononucleate cells; but at 7 days the intensity of labelling in the heterokaryons was greatly reduced relative to that found in mononucleate cells. It thus appears that although the phase of DNA synthesis is prolonged in the nuclei of heterokaryons, the rate of synthesis progressively falls, and eventually synthesis stops.

Under certain conditions the nuclei within the heterokaryons underwent fusion. The fused nuclei could usually be recognized by their greater size and by the fact that they contained many large nucleoli or condensations of chromatin. In many of the multinucleate cells only some of the nuclei underwent fusion, but in others all the nuclei in the cell fused together to produce one giant nucleus which sometimes had a bizarre shape (Fig. 12). Fusion took place not only between nuclei of the same kind but also between HeLa nuclei and Ehrlich ascites nuclei. This was demonstrated by fusing HeLa cells which

Fig. 15. Relationship between the proportion of heterokaryons showing nuclear fusion and the concentration of virus used to produce the heterokaryons. A, Infective virus at a concentration of 8,000 HAU/ml. B, C, D, Inactivated virus at concentrations of 80,000, 8,000 and 800 HAU/ml. respectively

the 5-day period, was caused by the continued activity of the virus. Indeed, the results indicated that the presence of large amounts of virus inhibited nuclear fusion. With increasing concentrations of virus the proportion of heterokaryons showing nuclear fusion on successive days was reduced; and, at the same dose, infective virus inhibited nuclear fusion more drastically than inactivated virus. It seems as if progressive nuclear fusion is the normal course of events in the heterokaryon, and that the inhibition produced by high doses of virus is a non-specific toxic effect. Preliminary experiments indicate that other toxic substances may also inhibit nuclear fusion. Since the term heterokaryon, as it is generally used, implies a cell with more than one nucleus, multinucleate cells in which the nuclei have fused together to form a single nucleus will be called synkaryons: homosynkaryons where nuclei of the same type have fused together, and heterosynkaryons where nuclei of different types have fused together.

The synkaryons continued to incorporate tritiated uridine into both nuclear and cytoplasmic RNA for at least 5 days at a rate not greatly different from that found in single HeLa cells in the same culture. Some of them also incorporated tritiated thymidine into DNA, although, over a 7-day period, the proportion showing labelling, and the intensity of the labelling relative to single HeLa cells in the same culture, progressively fell. There was, however, reason to believe that some synkaryons, including heterosynkaryons, were able to undergo at least one mitosis. In cultures containing both multinucleate and mononucleate cells it was observed that some of the cells rounded up in mitosis were very much larger than the rest. The cultures were therefore exposed for 18 h to colchicine at a concentration of 0.0025 per cent (w/v), and the karyotypes of the accumulated metaphases examined by the method of Rothfels and Siminovich<sup>7</sup>. It was found that some of the metaphase figures had up to 300 or more chromosomes, whereas the modal chromosome number for the HeLa and Ehrlich ascites cells was about 80. Moreover, some of these giant metaphases showed large numbers of both metacentric and telocentric chromosomes, including many long telocentrics. HeLa cells normally contain not more than one long telocentric chromosome, and frequently none at all<sup>8</sup>; and Ehrlich ascites cells normally contain very few metacentric chromosomes<sup>9</sup>. The presence of large numbers of both

metacentric and long telocentric chromosomes in the one cell therefore suggests that the cell originally contained both HeLa and Ehrlich ascites nuclei. Whether heterosynkaryons can produce clones of cells containing both human and murine chromosomes is the subject of current investigation.

In the experiments which we have described, an inactivated virus has been used to impose a form of artificial sexuality on mammalian tissue cells. Since the resulting hybrid cells synthesize protein, and both sets of nuclei synthesize RNA, these hybrids can be used to investigate problems of nucleocytoplasmic relationship which could hitherto be studied only in the heterokaryons of fungi or yeasts. Some features of the mammalian cell system perhaps warrant special comment. The remarkable fact that viable heterokaryons can be made with cells originating from different animal species means that a very wide range of genetic markers can be used to distinguish the two cell types. Indeed, the choice is limited only by the susceptibility of the cells to the virus used to produce fusion. The average number of nuclei per heterokaryon and the proportion of nuclei of each type can, within certain limits, be controlled. Preparations can be made in which 85 per cent or more of the cells are heterokaryons, and the ratio of multinucleate to mononucleate cells can be varied. Unlike fungi or yeasts, mammalian cells use thymidine as a specific precursor of DNA. This property makes mammalian cell heterokaryons eminently suitable for investigations on the regulation of DNA synthesis, as some of the present experiments show. Finally, autoradiographic and chemical techniques for the study of RNA metabolism in mammalian cells have now reached a moderate degree of sophistication: these procedures can be applied without modification to mammalian cell heterokaryons. There is, therefore, reason to hope that these heterokaryons will lend themselves to experiments which have hitherto not been possible in animal cells.

## PROGRESS OF PALAEOONTOLOGY IN CHINA

By YIN TSAN-HSUN

Division of Geology and Geography

CHOW MIN-CHEN

Institute of Vertebrate Palaeontology and Palaeoanthropology

AND

HSU JEN

Institute of Botany, Academia Sinica, China

MODERN scientific investigation of fossils in China dates back to the 1920's. The few palaeontologists made a good start in spite of the difficult working conditions. Many valuable monographic papers were published in *Palaeontologia Sinica*. The memoirs on Fusulinidae (Protozoa), Productidae (Brachiopoda) and others published by the journal are still among the classics of palaeontological literature.

But the investigations were confined to only a few groups of organisms including the fossils of plants, foraminifera, corals, brachiopods, trilobites and graptolites of the Palaeozoic era, Mesozoic reptiles and Pleistocene mammals. The materials were collected in a few districts with many regions of palaeontological interest unexplored.

Palaeontology has made considerable progress since New China was established in 1949. The number engaged in palaeontological investigations has increased from about 40 in 1949 to the present 400 to meet the growing demand in the fields of geological surveying, exploration, science and education.

In addition to *Palaeontologia Sinica*, two new periodicals, *Acta Palaeontologia Sinica* and *Vertebrate Palaeoasiatica*, have been published.

At present the Institute of Geology and Palaeontology of the Academia Sinica at Nanking is mainly concerned with the examination of plant and invertebrate fossils and biostratigraphy. The Institute of Vertebrate Palaeontology and Palaeoanthropology of the Academia Sinica

Fig. 1. Fossil of *Quercus semicarpifolia* Sm. of the Upper Pliocene Period of the Neogene Age found on the northern slope of Mt. Shisha Pangma in Tibet

Fig. 2. Fossil of *Quercus pannos*—H.-M. of the Upper Pliocene Period of the Neogene Age found at the northern slope of Mt. Shisha Pangma in Tibet

at Peking deals chiefly with the problems of vertebrate and human palaeontology and the closely related subjects of palaeolithic archaeology and vertebrate-bearing Caino-stratigraphy. Palaeontological laboratories are found in the Ministry of Geology, Ministry of Petroleum Industry, Ministry of Coal Industry, regional geological institutes, universities, colleges and museums.

Undergraduate and postgraduate courses in palaeontology are offered in the University of Peking, University of Nanking, Peking Geological College and other institutions of higher learning. The steady flow of trained personnel ensures the further development of this science.

What follows is a brief account of the work in the four main subdivisions of palaeontology: palaeobotany, invertebrate palaeontology, vertebrate palaeontology and palaeo-anthropology.

### Palaeobotany

The examination of plant fossils has an important bearing on the dating and correlation of the coal series and other continental or alternately marine and continental sediments, and on palaeogeographical and palaeoclimatological researches. In the past fifteen years progress has been made in the examination of megascopic plant fossils. Pollen and spore analysis, a valuable tool in dating the so-called 'dumb' or non-fossiliferous beds, has achieved notable results.

The Sinian and Cambrian spores discovered at Chihhsien County, Hopei Province, and Linhsien County, Shansi Province, indicate that some may belong to certain primitive land plants.

Sinian algae and post-Devonian species of *Chara* have been found in large quantity and are being investigated.

Devonian was the age when land plants began to flourish. Early Devonian plant fossils are known only in the province of Yunnan in China, and those of the Middle Devonian in Hunan, Szechuan, Kweichow and Kwangsi Provinces. Rapid progress has been made in the examination of the Late Devonian floras in the past few years. Their fossils are known in more than thirty localities in China; most were discovered after 1949. The presence of the Namurian rocks in South China and the Chilian

Mountains is chiefly demonstrated through examining the plant fossils. Great progress has also been made in the investigation of Late Palaeozoic floras, which comprises most of the palaeobotanical work done before 1949. Through detailed and comprehensive investigations of the large amount of new materials, our knowledge concerning the floral distribution, evolution and correlation of the Late Palaeozoic floras has increased.

From Triassic times, most of the sedimentary rocks in China are of continental origin and among them are many coal-bearing beds. Many problems in connexion with the subdividing and dating of these beds remain to be tackled, but examination of the microfossils and pollens and spores have yielded important preliminary results.

Attention has also been directed to the Quaternary pollens and spores. They are significant in elucidating the history of changes in the climate and vegetation of China during this period.

### Invertebrate Palaeontology

This is by far the largest and most varied of the fossil groups and has the most extensive application in geology. The examination of megascopic and microscopic fossils plays an important part in geological survey and the exploration of coal, petroleum and the ore deposits of iron manganese, phosphorus and aluminium.

Apart from providing material for stratigraphical correlations, invertebrate fossils also furnish important data for solving problems in palaeogeography, palaeoecology, evolution and migration. For example, the fossils of the fusulinids are abundant in China. In the early Carboniferous time they had already shown that the inland seas of China were connected with the Uralian and Mississippian seas.

In the middle Carboniferous time freer communication between them, especially between those of China and the boreal region, was maintained. Later in this period the fusulinid faunas of China showed close affinity with those of the Urals. At the same time they were quite close to those of southern Europe, central Asia and Japan, and also related to those of North America. In the early Permian time the fusulinids were well developed and widely distributed in the Tethys of South China and other inland seas connected with it, and some of the forms also made their appearance in the north-western part of North America. In the late Permian, at the time of world-wide regression, many parts of China were still experiencing transgression with small-sized fusulinids and other foraminiferas.

While the Devonian corals of South China are close to those of Western Europe and the Urals, those of inner Mongolia and North-east China are near to the faunas of eastern North America. The Carboniferous coral faunas of South China in the main succeeded those of the Devon-

ian, and the same relationship was retained. The Permian corals of China belong to the Tethys province.

The Palaeozoic brachiopods of China are quite characteristic and show strong local aspect. In certain places they are similar to the North American forms; in others, to those of Europe.

Much research work has been carried out on fossil molluscs and bryozoans. The formerly much neglected groups of freshwater gastropods, pelecypods and ostracods have received particular attention, and investigations in this connexion have made considerable headway. As to the trilobites and graptolites, in addition to much work on systematic description and biostratigraphy, attention has been directed to the zoogeography, ontogeny, phylogeny and microscopic structure of many of these groups, and significant results are being achieved.

Recently, under the direction and auspices of the Institute of Geology and Palaeontology, a book entitled *Fossil Invertebrata of China* has been published. It comprises the systematic revision, description and illustration of nearly all the more-than-6,000 species and sub-species of fossil invertebrates known so far in China. This work will no doubt contribute greatly to the development of palaeontological and biostratigraphical researches in China.

The Palaeozoic transgression of China, which was of wide extent and long duration, brought with it a vast array of rich marine invertebrate faunas. The Chinese palaeontologists have contributed a great service to geology in establishing stratigraphical columns and in subdividing and correlating the various Palaeozoic rock systems, series and stages. For example, results have been achieved in defining boundaries between Carboniferous and Permian, and between the Lower and Upper Permian.

### Vertebrate Palaeontology

Continentially deposited rocks, ranging in age from Devonian to Quaternary, were extensively developed in many parts of China with rich remains of fossil vertebrates. The streams and seas of the Devonian period were the centres of radiation of many groups of archaic fishes or fish-like lower vertebrates.

In southern China, Devonian redbeds corresponding to the Old Red Sandstones of northern Europe have yielded abundant remains of agnathans, placoderms, primitive sharks and bony fishes, many of which are of the same type as those of Europe or North America.

During the late Palaeozoic and Triassic times when the earlier reptiles and the reptilian ancestors of the mammals (or mammal-like reptiles) dominated the land, vast tracts of land emerged in China and were inhabited by these earlier tetrapods (Fig. 3).

Recently several expeditions have been organized to explore the richly fossiliferous beds in Sinkiang, Shansi and Yunnan, and large quantities of fossils have been excavated. The characters of faunas are in many respects common to those found in the southern parts of Africa. Fossils of Permian reptiles and Triassic amphibians (stegocephalians), both of which were unknown in China before, have been recovered. In almost every province various groups of Mesozoic reptiles have been found.

The widely distributed fossil remains of dinosaurs have been found in eastern China along the coasts as well as in the western gobis in northern Sinkiang. The Triassic dinosaurian faunas of Yunnan are nearly the

same as those of South Africa and western Europe; but those of the late Mesozoic are similar to North American forms. In Shantung, Kwangtung, Kiangsi, Hunan and Sinkiang, numerous reptilian eggs, many of them of dinosaurs, were collected.

In recent years many good specimens of marine reptiles and some Cretaceous flying reptiles have also been found. Remains of the former have been located recently in the Himalayas in Tibet. Of the Cainozoic or 'age of mammals', progress has been made in recent years with the discovery of many fossils of archaic mammals. Palaeocene mammals are known in Kwangtung, Hunan, Kiangsi and Sinkiang. Some of these early Cainozoic mammalian faunas (Eocene) are similar to those of Korea, Burma and Pakistan, and some quite similar to those of North America (Palaeocene and earlier Eocene), and the fish fauna of that time included many forms now living in south-eastern Asia, such as some of the islands of Indonesia. The general aspects of late Tertiary mammalian faunas of China resemble those now found in Africa rather than the modern Chinese faunas.

Examination of Quaternary mammals has made rapid progress as a result of its intimate connexion with engineering geology and anthropology. Since the middle Pleistocene the mammalian faunas of South China have been essentially the same as those of the countries in south-east Asia.

### Palaeoanthropology

Palaeoanthropology deals with the origin and evolution of man. All the earliest human fossils so far known in the world were found in Asia and Africa, such as *Atlanthropus* (Algeria), *Pithecanthropus* (Java) and *Sinanthropus* (China). The many important palaeoanthropological discoveries made in Africa in recent years have attracted world-wide attention and have aroused keen interest among Chinese scientists.

China is one of the few countries in the world particularly rich in human fossil remains (Figs. 4 and 5). In the past fifteen years many important new discoveries have been made in various parts of the country. Among these new findings the Tzeyang Man, found at Tzeyang County in Szechuan, and the Liukiang Man of Liukiang, Kwangsi,

Fig. 3. A huge block with ten skeletons of mammal-like reptiles of the Late Triassic Age is being excavated at the Dzungaria Basin in Sinkiang during the 1964 palaeontological expedition of the Academia Sinica

Fig. 4. Side view of the mandible of *Sinanthropus lantienensis* ( $\times c. 1$ )

Fig. 5. Dorsal view of the mandible of *Sinanthropus lantienensis* ( $\times c. 0.75$ )

are of *Homo sapiens* type, corresponding to the Cromagnon type man of Europe. At Mapa in Kwangtung, and Tingtsun in Shansi, remains of the fossil man of the Neanderthal type were unearthed. In the well-known locality at Choukoutien new materials of *Sinanthropus pekinensis* or

Peking Man have also been excavated. In 1963 and 1964, at Lantien, near Sian in Shensi, a new type of *Sinanthropus*, including a well-preserved skull cap, was discovered. At many of these and other localities, a large number of cultural remains of early man, mainly palaeolithic implements, were found.

In close connexion with the examination of the origin of man is the examination of fossils of other higher primates. Some years ago at Liucheng in Kwangsi Province, a great number of fossils of *Gigantopithecus*, including three well-preserved mandibles and thousands of teeth, were excavated from the Lower Pleistocene cave deposits. These discoveries have aroused great interest in the scientific world. Palaeontologists and anthropologists still differ greatly as to whether *Gigantopithecus* was a kind of giant man or giant ape. The Chinese scientists who have examined the material also hold varying views. Some think that *Gigantopithecus* is a hominid of pre-homotype; others maintain that it is a member

of the Pongid family.

The discovery of the remains of *Dryopithecus* in Yunnan some years ago has supplied an important link in the evolution of man in China.

### Conclusion

Palaeontological investigation calls for a high degree of international co-operation. Constant exchange of information and experience is indispensable for the palaeontologist wherever he may be. Many of the fossils found in China are not only similar to those of her neighbouring countries, but also show close affinity with those recovered in other continents.

In some cases, fossils of constituent parts of the same kind of organisms are found separately in different countries. Here the need for international co-operation is obvious.

Besides, there are many problems in palaeontology, such as the origin and dispersal of many a group of organisms, the correlation of biota of the different regions of the world, and the investigations of fundamental principles of organic evolution—problems on which we cannot obtain a comprehensive view or reach a sound conclusion without access to relevant information gathered from other parts of the world. Frequent contact between palaeontologists of various countries will not only promote progress in science but also further strengthen the friendship and solidarity of the world's people.

## OBSERVATION OF RADIOACTIVE FALL-OUT IN NIGERIA UP TO 1961

By DR. B. N. C. AGU

Physics Department, University of Ibadan, Nigeria, and Director of Federal Radiation Protection Service

THE deposition of fission products from nuclear test explosions has been measured since 1954 by R. N. Crooks *et al.*<sup>1</sup> for 25 stations in many parts of the world. The measurements assessed the quarterly deposition of strontium-90 in rain-water and the ratio of caesium-137 to strontium-90 in the samples. Their results for Lagos, Nigeria, up to the middle of 1959 indicated low levels of fall-out, consistent with the fall-out pattern expected for an equatorial region from the world-wide fall-out distribution<sup>2</sup>. However, because of the close proximity of the French Nuclear Test Site at Reganne to the densely populated countries of tropical Africa the possibility of

local fall-out occurring in these countries became a matter of concern and it was decided to make specific measurements.

Systematic fall-out sampling was started in Nigeria in October 1959, four months ahead of the first nuclear explosion at Reganne. Six sampling stations were set up with the aid of the United Kingdom Atomic Energy Authority at airport meteorological stations situated at Maiduguri, Kano, Kaduna, Sokoto, Lagos and Port-Harcourt. These stations were chosen to provide a fairly good coverage for the whole territory of the Nigerian Federation of about 800,000 km<sup>2</sup> in area.

Altogether four nuclear explosions above ground were recorded during the Sahara test series, on February 13, April 1 and December 27, 1960, and on April 25, 1961. Only the first of these explosions resulted in significant fall-out in Ghana<sup>3</sup>, Nigeria, Israel<sup>4</sup>, Czechoslovakia<sup>5</sup>, Panama Zone<sup>6</sup>, United Kingdom<sup>7</sup> and a few other places, while the third and fourth explosions gave rise to only limited fall-out in Nigeria. The nearest Nigerian sampling station to the Sahara Test Site was at Sokoto, situated 1,300 km south-south-west of Reganne, and the farthest was at Port-Harcourt, 2,200 km to the south-south-west. However, the highest fall-out observed during the French test was at Maiduguri in Northern Nigeria, about 1,900 km south-west of Reganne.

**Meteorological factors.** The Nigerian Meteorological Services produced daily upper air charts for the region during the period of the Sahara nuclear tests. The trajectories showing the positions at various times of air parcels from Reganne on February 13 at 0600 G.M.T.—the time of the first explosion—were drawn for heights of 3,000 m, 6,000 m, 8,000 m, 10,000 m and 12,000 m above sea-level. For mid-day of February 13, 1960, 6 h after the first explosion, the charts showed an unusual wind pattern (Fig. 1). At Reganne the upper winds were mainly strong westerly, but farther to the east there was a change to north-westerly winds in layers around 10,000 m above sea-level. From the observed wind patterns and the dates of arrival of the radioactive debris at the various sampling stations, most of the radioactive clouds which left Reganne in the layer between 6,000 and 12,000 m reached Northern Nigeria in about 30 h.

Thus, the changes in direction with height, and the high wind-speeds, had the effect of carrying radioactive clouds relatively quickly to places in West Africa where, based on the more usual wind patterns, little fall-out had been expected.

**Fall-out measurements.** The three sampling methods used by the United Kingdom Atomic Energy Authority for obtaining fall-out samples from specific test explosions were adopted for Nigeria. The first method, which provides a sample of deposited particulate fall-out (often referred to as a 'sticky-paper' sample), consists of exposing

horizontally a 30 cm × 15 cm sheet of adhesive cellulose tape for a period of 24 h. In the second method, air is drawn continuously through a filter-paper of about 5 cm diameter, so that all particles in a known volume of air are trapped on the filter-paper. In the third, a daily rainfall sample is collected.

After installation, test runs were made with the apparatus to check procedures and establish background levels, and the stations were then held in readiness. On February 13, 1960, the date of the first nuclear explosion at Reganne, all stations were started and 24-h samples were flown to Kano where a preliminary assessment was made with an Ericsson type 1320B monitor. The samples were then sent by air to the United Kingdom for measurement at the Atomic Weapons Research Establishment, Aldermaston.

For the deposition samples of moderate activity, the standard counter was a 6 in. × 6 in. anthracene scintillator, which could detect a minimum activity of 920  $\mu\text{c./m}^2$  at 10 per cent counting efficiency. For low-activity samples, a gas-flow counter with anti-coincidence ring was available which had 40 per cent counting efficiency. A 2-in. end-window Geiger counter, type 2B2, was used to count air-filter samples of moderate activity, while a low background counter with anti-coincidence ring was available for samples of low activity. The water samples were first treated to concentrate their activity into a smaller bulk and then counted with the same equipment used for the air-filter samples.

The daily dispatch of samples to Aldermaston was continued until the preliminary assessment at Kano showed no appreciable fall-out activity. In general the samples arrived at Aldermaston several days after collection, and the activity of each sample was extrapolated back to the mid-time of the collection period by means of a  $t^{-1.2}$  decay curve characteristic of mixed fission products.

**Results.** No results were obtained from rainfall samples during the week following the first explosion as no rain fell in the northern part of Nigeria. Light showers occurred in Lagos and Port-Harcourt on February 17, and again at Port-Harcourt on February 19, but the level of activity in the rain-water collected was insignificant.

Fall-out was first detected at Maiduguri in Northern Nigeria on February 14, 1960, where an activity of 12,100  $\mu\text{c./m}^2$  was recorded on the sticky-paper sample. From that time onwards, the daily arrival of radioactivity decreased rapidly to less than 0.5 per cent of this maximum value in about a week, as shown in Fig. 2. Sokoto showed a similar pattern, but this began a day later than at Maiduguri and had a lower peak-value of 1,500  $\mu\text{c./m}^2$  for the sticky-paper sample. Farther south, at Lagos and Port-Harcourt, the same pattern of a sudden start at a high activity and a steady decrease to the normal background of less than 1  $\mu\text{c./m}^2$  was followed three days after the first test explosion at Reganne.

However, at Kano and Kaduna, both also in the north, a slightly different pattern was observed. In these two places, the peak fall-out was reached on February 15, one day after the first arrival of radioactive debris at these stations. Thereafter, the decrease in activity followed the usual pattern.

No explanation is offered, but it is interesting to note that the air-filter sample histograms (apart from that for Sokoto) have profiles which are consistent with this effect.

The second Sahara test explosion, on April 1, 1960, produced no detectable fall-out in any part of Nigeria, although workers in Israel<sup>4</sup> and Ghana<sup>3</sup> observed some fall-out from this explosion. The third test, on December 27, 1960, gave rise to very low fall-out activity of the order of 4  $\mu\text{c./m}^2$  for sticky-paper samples in all parts of the country, while the highest value for filter-paper samples, namely, 0.026  $\mu\text{c./m}^2$ , was collected at Kaduna. For the fourth test, on April 25, 1961, the sticky-paper samples showed no activity; while the maximum filter-paper sample was 0.0049  $\mu\text{c./m}^2$  at Kano. During this test rain-water samples were obtained for Maiduguri

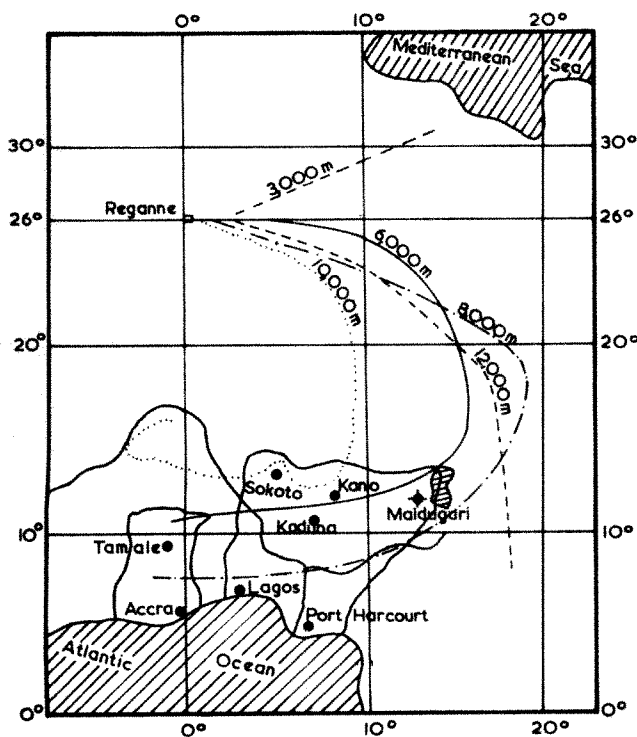

Fig. 1. Trajectories at constant height of air parcels from the test site at Reganne

and Port-Harcourt, where  $12.2 \mu\text{C}/\text{m}^2$  and  $3.1 \mu\text{C}/\text{m}^2$  respectively were recorded.

**Radiological considerations.** In estimating the dose which could be received by the gonads from fall-out deposited on the ground, conditions were assumed which would result in maximum exposure. The case was taken of a man living and sleeping in the open, who is exposed to radiations from a smooth infinite plane. In these conditions the dose to the gonads from the highest recorded levels of deposited fall-out would be only one-fifth of the average annual dose (0.1 rem) to individuals from natural causes.

When considering the possible hazard from strontium-90 it is important to remember the agricultural conditions prevailing at the time of the first test explosion. The main dietary source of strontium-90 is milk, and this element enters the food-chain principally from the grazing of cattle on contaminated pastures. Surface vegetation was very limited in Northern Nigeria during the period of the test, and hence the intake of strontium-90 by grazing cattle would be very small. Further possible sources of strontium-90 would be water from open pools and food exposed in the open. At the time of the explosions there were few standing crops which could be thus contaminated and most water is obtained from wells which are covered and so protected from contamination by fall-out.

**Discussion.** It is of interest to note that the sticky-paper method of particulate sample collection used in Nigeria was also used by the Israeli workers<sup>4</sup>. It is considered that this method is to be preferred to that of Ward and Marr<sup>3</sup>, who collected fall-out in Ghana by sweeping up the dust from a measured area of a flat, concrete roof, a technique which is liable to lead to an underestimate due to losses in the sweeping-up process. Both methods, it should be noted, will tend to overestimate the fall-out level by collecting 'secondary fall-out', that is, fall-out which has been deposited once but has been stirred up by human actions or winds. The brown color-

Fig. 3. Air-filter sample activities ( $\mu\text{C}/\text{m}^3$ )

tion apparent in some of the Nigerian sticky-paper samples was taken to be evidence of this phenomenon. However, this factor alone is not sufficient to account for the high fall-out activity observed in Nigeria during the Sahara tests, Fig. 2.

For the filter-paper samples, the methods used in Ghana, Nigeria, Israel, Czechoslovakia<sup>5</sup> and Panama Zone<sup>6</sup> were identical, and hence direct comparison of the results of fall-out measurements in these countries can be made. Some results are plotted in Fig. 3 which show that the filter-paper samples for Maiduguri in Nigeria gave the highest value of fall-out so far reported from the Sahara test.

In the United Kingdom, Israel and Czechoslovakia, fall-out was detected from radioactive debris which had been carried round the world. The small increases noted in some Nigerian air-filter samples of February 18, 1960, could not have originated from this source, since it would have required westerly winds of up to 320 km/h to carry the radioactive clouds round the world and back to Nigeria again in four days. This speed is far in excess of the 65 km/h estimated for the upper troposphere winds that brought the 'second-time-round' fall-out over Israel<sup>4</sup> during March 9-10, 1960.

I thank the Director of the Nigerian Meteorological Services and his staff for the collection of the samples, Mr. N. Pearce and certain members of the Radiation Measurements and Instrumentation Branch, Aldermaston, and the United Kingdom/Nigeria Scientific Committee on Fall-out Monitoring for their assistance.

## OBITUARIES

## Dr. B. G. Gates

DR. BENJAMIN GEORGE GATES, who was the controller of research and development of the Australian Defence Scientific Service in the Department of Supply, died suddenly on December 1, 1964, at the age of sixty. He collapsed at a farewell retirement dinner given by his colleagues at the rooms of the Royal Commonwealth Society in Melbourne. He had a distinguished career in Scientific Research and Development, and for about thirty years was concerned with science in its application to defence.

Gates graduated from the City and Guilds College of the University of London in electrical engineering in 1924, and later was awarded a Ph.D. Between 1924 and 1935 he served with various industrial organizations, including Messrs. Johnson and Phillips, Ltd., London; Metropolitan Vickers, Ltd., Manchester; the British Electric Transformer Co., London; and the British Electrical Research Association. In 1935 he joined the Radio Department of the Royal Aircraft Establishment at Farnborough. In this establishment he first became acquainted with some of the scientific problems peculiar to defence, and soon made his own contribution to their solution.

He was concerned with the provision of reliable radio communication between aircraft and aircraft, and between aircraft and the ground; the comparative ease with which such communication is carried on to-day gives little indication of the magnitude of the problems which had to be overcome. Not the least of these was that of speech modulation of the radio transmitter in the very high noise-levels encountered in aircraft, and it was in this field that he made one of his most noteworthy contributions. Dr. Gates joined the Radio Department of the Royal Aircraft Establishment as a scientific officer, and within a decade he was head of that Department.

In 1950 he joined the Australian Defence Scientific Service as the controller concerned with the management of the Woomera Rocket Range, for which appointment he was specifically, and unequivocally, recommended by the late Sir Henry Tizard. It will be recalled that some three years earlier it had been agreed by the British and Australian Governments that a rocket range should be set up in Australia for the development of a long-range rocket, which would form the basis of a deterrent weapon system. The range at Woomera was planned originally for this purpose, and a rocket based on the German V2 of the Second World War was conceived under the name *Hammer*. Within a year, however, as a result of a change in policy of the British Government, this project was cancelled, and it was decided to proceed with the Woomera Range for the development not of a deterrent weapon system but of a series of ground-to-air and air-to-air weapons for direct defence. Dr. Gates was concerned with the planning and building of Woomera for this modified requirement, and he supervised its growth as a general purpose range capable of handling almost any project requiring space and accurate measurement. So in due course the range was readily adaptable to handle the *Blue Streak* project when, due to another reversal of policy by the British Government, the deterrent weapon project was revived. Again on cancellation of this project as a weapon, in its turn, the range was found to be readily made suitable for the launching of satellites based on the *Blue Streak* rocket, under the auspices of the European Launcher Development Organization of which Australia is a member.

Dr. Gates was concerned, as 'general manager', not only with the scientific and technical requirements for the range itself, but with all the support which such a facility

necessitates. These supporting facilities included the recruitment of some hundreds of graduate scientists and the further training of many of them overseas for periods of up to two years. The provision of a town with schools, shops, a hospital and so on was necessary to house range staff and their dependants, and a supporting air service had to be arranged in co-operation with the Royal Australian Air Force. Clearly, then, the Woomera Rocket Range owes much to the effective management by Dr. Gates in those early days.

In 1955 he was appointed 'controller of research and development' in the Australian Defence Scientific Service and deputy chief scientist (deputy chief executive), and was involved until his death with the build-up and use of resources capable of providing modern weapons and equipment for the Australian Fighting Services. Partly to train personnel for this purpose, and partly to provide a useful weapon, the British Army's anti-tank weapon *Malkara* was successfully completed.

In addition to the management of these research and development resources for the Australian Services, and the supervising of the Australian Defence Scientific Service as a whole (including the Rocket Range and associated activities) during the absences overseas of the Chief Scientist, Dr. Gates was very closely involved in managing a guided-weapon project, *Ikara*, for the Royal Australian Navy. The successful completion of this sophisticated system, which accurately delivers a self-homing torpedo to a desired location at sea, is due in large measure to Gates's conscientious supervision. Gates had a wide knowledge of those branches of science concerned with defence and, in the field of electrical engineering and electronics, this knowledge was encyclopaedic. He was a most pleasant colleague with whom to work and was unruffled in a crisis; his loss will be deeply felt. He leaves a wife, a daughter and a son.

W. A. S. BUTEMENT

## C. S. Franklin, C.B.E.

CHARLES SAMUEL FRANKLIN, one of the greatest pioneers of radio telecommunications, died on December 10, 1964, at the age of eighty-five. He will always be honoured for the prominent part he played in the small band of engineers associated with Guglielmo Marconi in the development of wireless—now radio—communications and associated valve techniques, during the first half of this century.

Franklin was born in 1879 and received his engineering and scientific training at the Finsbury Technical College under Prof. Sylvanus Thompson. After gaining some experience in electrical work, first at Manchester and afterwards with the Norwich Electricity Co., he joined the Wireless Telegraph and Signal Co. in 1899. This organization later became Marconi's Wireless Telegraph Co., with which Franklin remained associated until his retirement in 1939.

After a period in South Africa, where he helped to introduce wireless communication as a military aid during the Boer War, he sailed with Marconi across the Atlantic in 1902 to demonstrate the reception of wireless messages up to a range of some 1,550 miles from the Poldhu transmitting station in Cornwall. This was followed by a long personal association between Franklin and Marconi, during which were laid the foundations of modern world-wide radio communications.

Beginning with specially designed spark transmitters, Franklin was quick to appreciate the possibilities of the thermionic valve as a generator of radio frequency

oscillations, as well as a regenerative receiver of high sensitivity, and as early as 1913 he had filed patents covering techniques in this field. During the period 1916-20, the short-wave beam principle was developed, and one example of this was the rotating parabolic reflector station at Inchkeith, transmitting on a wave-length of 6 metres and demonstrating the possibilities of a radio beacon for navigation purposes. The Franklin master oscillator circuit of high stability formed an essential part of the subsequent development of the short-wave beam communication system.

During 1923-24, he installed a short-wave station at Poldhu, using a wave-length of nearly 100 m and directing the beam towards Marconi's yacht cruising in the South Atlantic. These experiments illustrated the practical possibilities of short-wave radio communication over long distances—by way of the ionosphere as we know to-day. In this connexion the Franklin beam aerial system was designed which, in one form or another, has formed the basis of short-wave world-wide communications, including broadcasting, for the past forty years. A necessary part of such a system was the associated development of the low-loss coaxial cable for the transmission of the very-high-frequency currents to and from the aerial arrays.

Franklin was also closely associated with broadcasting, and assisted in the design and installation of the transmitter and aerial system at London's first broadcasting station, then known as 2LO. Later he designed the transmitters and aerials for the B.B.C.'s station at Alexandra Palace which was used for the world's first regular television service. Although Franklin formally retired in 1939, he remained for some years as a research consultant to the Marconi Co.

Among the awards which came to Franklin in the course of his career were the Morris N. Liebmann Memorial Prize of the Institute of Radio Engineers (N.Y.) in 1922; the James Alfred Ewing Medal of the Institution of Civil Engineers (1936); and the Faraday Medal of the Institution of Electrical Engineers (1949) for "his distinguished work in radio engineering, and more particularly for his development of the beam aerial and other devices that made long-range high-frequency communication a practical possibility". In 1949, also, he was created a Commander of the Order of the British Empire.

Franklin was possessed of a modest and quiet but persistent manner; he was known and respected by all the scientists and engineers connected with the early history of telecommunications in the evolution of which he played such an outstanding part. R. L. SMITH-ROSE

## NEWS and VIEWS

### U.K. Atomic Energy Authority Weapons Group:

Mr. E. F. Newley, C.B.E.

MR. E. F. NEWLEY has been appointed director of the U.K. Atomic Energy Authority Weapons Group. Mr. Newley gained the degrees of B.Sc. (Mech. Eng.) and M.Sc. at the University of London, and spent the early part of his career at the Post Office Research Station, Dollis Hill. In 1949 he joined the Admiralty as a senior principal scientific officer, and left in 1955 to take up an appointment as deputy chief engineer at the Atomic Weapons Research Establishment, Aldermaston. Later he became chief of warhead development at Aldermaston and in 1959 was appointed deputy director, which position he has held until now.

### Chemistry in Brunel College of Advanced Technology:

Prof. K. S. W. Sing

DR. K. S. W. SING, head of the Department of Chemistry and Biology at Liverpool College of Technology, has been appointed to the chair of chemistry at Brunel College of Advanced Technology. Dr. Sing was educated at Teignmouth Grammar School and the University College of the South West of England (now the University of Exeter). In 1945 he gained a B.Sc. of the University of London in special chemistry with first-class honours, and remained at Exeter for a further three years as a research student studying the thermal decomposition of aluminium hydroxide, under the direction of Dr. S. J. Gregg. Dr. Sing was awarded a Ph.D. by the University of London in 1949 for his thesis dealing with adsorption of porous solids with particular reference to the adsorbents produced by heating gibbsite. After leaving Exeter in 1948, Dr. Sing spent a year in the research department of Imperial Chemical Industries, Ltd., Billingham. In 1949 he joined the staff of the Royal Technical College, Salford, where he was successively lecturer and senior lecturer. In 1956 he moved to Liverpool College of Technology, and under his headship the Department of Chemistry and Biology—already in a thriving condition—increased greatly in size, both in terms of accommodation and staff and student numbers, to the point where it is now one of the major departments of its type in a Regional College. Possibly the most striking development has been the increase in the amount of research carried out in the Department, much of it

sponsored by local industry. Dr. Sing's own research has included perhaps the first systematic attempts to investigate the conditions of formation of silica gel in relation to its surface properties, and investigations of the ageing of precipitated alumina at room temperature. His present interests include gas adsorption and the surface and structural properties of alumina and various mixed oxide catalysts.

### Brewing and Applied Biochemistry in the Heriot-Watt College, Edinburgh:

Prof. D. J. Manners

DR. D. J. MANNERS has been appointed to the chair of brewing and applied biochemistry at the Heriot-Watt College, Edinburgh, in succession to the late Prof. I. A. Preece (204, 1033; 1964). Dr. Manners was educated at Fitzwilliam House, Cambridge, where he obtained honours in the Natural Sciences Tripos (Biochemistry) in 1949 and a Ph.D. degree in 1952 for his research on carbohydrate biochemistry. He was appointed to a lectureship in chemistry at the University of Edinburgh in 1952 and to a readership in 1964. Dr. Manners's research interests have included investigations of the molecular structure of glycogen and polysaccharides from protozoa, algae and yeast, on glycogen storage diseases, on starch-degrading enzymes and on enzyme systems in marine algae. On the basis of this work he was awarded the Meldola Medal in 1957, and the D.Sc.(Edin.) degree in 1960. He was elected a Fellow of the Royal Institute of Chemistry in 1958, and has recently been appointed to the Editorial Board of the *Biochemical Journal*. His present research projects include several which are of direct interest to the brewing and related industries, so that the close links already established by Prof. Preece between the Heriot-Watt College and those industries will be maintained. It is expected that the College will attain university status at an early date and that, under the direction of Dr. Manners, the Brewing and Applied Biochemistry Department will take a full part in these developments.

### Sociology in the University of Bristol:

Prof. M. P. Banton

THE University of Bristol, the most recent of the established English universities to introduce courses in sociology, has appointed Dr. M. P. Banton to the newly

established chair of sociology. Dr. Banton was educated at King Edward's School, Birmingham, the University of Glasgow, and the London School of Economics. Appointed Noel Buxton research student in the Department of Social Anthropology, University of Edinburgh, in 1950, he undertook a study of African and West Indian immigration to Britain for which he was awarded a Ph.D. As Nuffield Research Fellow he then conducted an investigation of rural-urban migration and tribal life in Freetown, Sierra Leone. Dr. Banton was appointed assistant in social anthropology at Edinburgh in 1953, advancing to lecturer in 1955, to reader in 1962, and graduating D.Sc. in 1964. In 1959 he was secretary to the organizing committee for the Darwin Centennial Conference held in Edinburgh, and edited the Conference *Proceedings*. From February 1962 until January 1963 he was visiting professor of political science in the Massachusetts Institute of Technology where he was concerned with courses dealing with political and social development in Africa. In the 1964 Malinowski Memorial Lecture, delivered at the London School of Economics, Dr. Banton discussed the inter-relations of social anthropology and sociology, maintaining that in many situations it was more confusing than helpful to refer to them as separate subjects. In recent years he has undertaken research into British behaviour towards coloured people, and into the social characteristics of police work in Scotland and the United States. His concern to study interpersonal relations in sociological terms while drawing equally on the conclusions of social psychology and anthropology is most apparent in his recent work. Sociology teaching will start at Bristol in October 1966 and it is hoped to promote research on a broad front.

#### U.S.S.R.—United States Joint Desalination Scheme

A SIGNIFICANT step was taken on January 26 towards closer collaboration between the U.S.S.R., the United States and the International Atomic Energy Agency, when it was officially announced that the two countries had agreed to co-operate in the field of desalination. The agreement, which had been concluded between the two countries on November 18, 1964, and signed by Mr. A. I. Alexandrov, representing the U.S.S.R., and Mr. F. K. Hefner, representing the United States, provides for wide scientific and technical co-operation and for an exchange of scientific reports and other documents, periodic scientific meetings and visits of experts on a reciprocal basis. In order that the International Atomic Energy Agency and its members should receive benefits in full measure from this operation, it is stated in the agreement that the parties will give the Agency copies of accounts, reports and other documents which they exchange and also, in appropriate cases, invite observers to symposia and scientific meetings held by the parties.

#### Industrial Needs for Scientific Manpower

FIRST returns are now coming in from 11,000 employers in all sections of British industry who have been asked to participate in a survey aimed at providing adequate knowledge of the future needs of industry for scientific and technological manpower as a pre-requisite to meeting those needs. It is being carried out by the Ministry of Labour for the Committee on Manpower Resources for Science and Technology. This Committee, under the chairmanship of Sir Willis Jackson, replaces the former Committee on Scientific Manpower of the Advisory Council on Scientific Policy for whom similar surveys were carried out by the Ministry of Labour in 1956, 1959 and 1962. The latest enquiry is addressed to all establishments employing 500 workers or more and to a sample of those employing less than 500. To obtain more accurate information on the nation's technical manpower resources the range of this enquiry has been extended to cover "technicians and other technical supporting staff", as well as fully qualified scientists and technologists. The importance of this

supporting staff is being increasingly recognized and information about its supply and demand, complementary to that for professionally qualified staff, is essential. About 6,000 of the employers who have been approached are in the manufacturing industries, but service industries, including local and national Government Services, are also covered. The British Employers' Confederation, the Federation of British Industries and the National Association of British Manufacturers are giving full co-operation. Reports of the earlier surveys brought together, on a statistical basis, data on the output from the educational system, and of the utilization in employment of scientifically and technologically qualified manpower, together with forecasts three years ahead of the needs for this category of manpower. The results of the enquiry will be made available to the Committee on Manpower Resources for Science and Technology and published later this year.

#### Medical Research Council:

##### Brain Metabolism Research Unit

THE Medical Research Council has set up a Brain Metabolism Research Unit in the Department of Pharmacology, University of Edinburgh Medical School. The Unit, which will be under the honorary direction of Prof. W. L. M. Perry, aims to undertake experimental and clinical studies of the metabolic pathways of certain amino-acids and other substances in the brain and tissue fluids. The action of psychotropic drugs on these pathways will be used as a means of trying to determine whether there are metabolic defects in the various psychoses and ultimately whether such defects can be corrected.

##### Unit for Research on the Chemical Pathology of Mental Disorders

DR. F. A. JENNER has been appointed physician-in-charge of the Council's Unit for Research on the Chemical Pathology of Mental Disorders in the Department of Physiology, University of Birmingham Medical School, and at the Hollymoor Hospital, Birmingham, following Prof. I. E. Bush's resignation. The Unit will continue to carry out research into the development of new biochemical and other experimental methods for detecting chemical abnormalities in patients, but Dr. Jenner's appointment will lead to an increased emphasis on clinical research and a more concentrated study of physical problems associated with periodically recurring mental disorders.

#### Investment in Scientific and Technological Research in India

IN their paper, *Investment in Scientific and Technological Research during the Fourth Five Year Plan*, Dr. S. Husain Zaheer, A. Rahman and N. Sen discuss the quantum of investment in science and technology, particularly in the light of two investigations made by the Survey and Planning of Scientific Research Unit of the Council of Scientific and Industrial Research (Pp. 31. New Delhi: Council of Scientific and Industrial Research, 1964). The first examination indicated that support by State Governments had been limited to research on agriculture and animal husbandry, with a surprising neglect of research on industrial, technological and natural resources. It also showed that the support of the Central Government in several sectors was also unbalanced and the rates of growth of various sectors differed widely. The second investigation revealed an increase of 15–20 per cent per annum in scientific and technical personnel in the developed laboratories, and a more rapid increase in the younger laboratories. The cost of administration varied between 8 and 12 per cent per annum in these national laboratories, and recurrent expenditure was increasing by 12–20 per cent per annum, while capital expenditure, though varying from laboratory to laboratory, could be

estimated fairly accurately over a term of years. The average cost per scientist was also fairly steady, and a rate of growth of 10 per cent in investment was indicated. From these investigations, assumptions are made which lead to projections of expenditure on scientific and technological research, by the Central Government, and by the State Governments; of expenditure by the Central and State Governments on research in universities; and of expenditure by organized industry on research. For university research, figures of Rs. 46.0 million and Rs. 116.8 million, respectively, are suggested for the first and final years of the Plan, or Rs. 388 million in the university sector (4.4 per cent of the total investment in scientific research) during the quinquennium. Expenditure by organized industry is put at Rs. 193.4 million in 1966-67, rising to Rs. 343.1 million in 1970-71, or an investment of Rs. 1,317 million during the period, 14.8 per cent of the total investment on research.

### Art and Design

THERE is a widespread and growing interest in design among manufacturers and the general public, and in recent years the majority of students who have successfully completed a period of training at one of the recognized art schools have been able to find employment in some sphere of design. There is also a steady demand for art teachers. In most branches of art other than design, however, the openings occurring each year are to be reckoned in tens, not hundreds, and it takes time for even the most talented to establish themselves as free-lance artists. This information is given in a revised illustrated edition of *Art and Design* (Central Youth Employment Executive, *Choice of Careers*, No. 103. Pp. 55. London: H.M. Stationery Office, 1964. 2s. net). The booklet groups occupations in design under the following headings: the graphic arts; fashion design; package design; product design; design for woven textiles and printed materials; design for entertainment (set design, animated films and television). Particulars of educational qualifications for designers, professional training, examinations, cost of training, openings, and some indication of salaries, are also given.

### The National Museums of Southern Rhodesia

THE major task during 1963 for the National Museums of Southern Rhodesia was the installation of interior fittings and displays in the three new Museums (Report of the Trustees and Directors of the National Museums of Southern Rhodesia for the year ended December 31, 1963. Pp. 32. Salisbury: National Museums of Southern Rhodesia, 1964). In the initial planning of this work adequate display teams were envisaged. As so often happens in the museum field, in the event this was not forthcoming, though at the end of the year it was arranged that the opening of the three Museums would be in 1964. The Councils of the City of Bulawayo, the City of Salisbury and the Town Council of Umtali all made provision for the sites of the new buildings and in many ways have played a major part in making these developments possible. The three Councils continue to provide maintenance grants. In spite of their preoccupation with the moves to the new buildings the staff have been able to continue research work, as is testified by a series of publications. It is also pleasing to note that Captain E. F. Boulton continues as honorary keeper of arms and antiquities at the Umtali Museum.

### Natural History in the U.S.S.R.

THE weekly journal of the Russian book trade, *Novye Knigi* (No. 51; 1964), announces the forthcoming publication of a series of pocket-sized popular handbooks on the mammals, birds, reptiles, fishes, insects, trees and shrubs, grasses and flowering plants, and rocks and minerals of the U.S.S.R. The works, in Russian, are intended for the use of older school-children, amateur

naturalists and tourists, and will be extensively illustrated in colour. The edition is 50,000 copies of each, length 20 printers' sheets, price 1r. 75k. (about £1). The first book of the series, on mammals, will be published in 1965 and the others over the next three years.

### International Subject Bibliographies

*Maxwell's International Subject Bibliographies* No. 1 deals with electronics, including control engineering, covering the period 1960-63, but excluding medical and biological electronics and books on computers published in 1963-64, for which a special bibliography (No. 29) is available. *Special Subject Bibliography* No. 6 covers orthopaedics, including rehabilitation of the physically handicapped, but excluding myology, physical education in general and rehabilitation of the blind and deaf. This second edition covers the period 1961-63. *Special Subject Bibliography* No. 10 covers electrochemistry, including polarography, 1953-May 1964; No. 19 covers reinforced plastics, including polyester resins, plasticizers and glass film products, January 1960-June 1964; and No. 28 deals with machine tools and machine tool design, excluding drilling, polishing, cutting, grinding and pressing tools, which are covered by No. 9. This second edition refers to the period 1961-May 1964 (Oxford: Robert Maxwell and Co., Ltd.; Long Island City, N.Y.: Maxwell Scientific International, Inc., 1964).

### Wheat Research in Australia

THE annual report of the Wheat Research Unit of the Commonwealth Scientific and Industrial Research Organization for 1963-64 is a summary of work in progress, illustrating very clearly the possibilities of applying modern techniques to the investigation of the complex mixture of protein and carbohydrate that is the basis of bread dough (Pp. 15. Ryde, N.S.W.: Commonwealth Scientific and Industrial Research Organization, 1964). In fact, almost the entire effort of the laboratory is being devoted to the separation of homogeneous fractions of the complex in amounts sufficient for baking tests. The main research effort is concerned with the fractionation of the proteins comprising the gluten complex. A many-sided attack on this difficult problem is being made, using the techniques of column chromatography, starch-gel electrophoresis and gel-filtration. A particularly interesting aspect is the examination of the effect of ionic strength on the behaviour of gluten proteins during gel filtration on 'Sephadex'. This should ultimately provide a better understanding of the role of gluten proteins in relation to the physical properties of dough. Preparations of flour gum have been shown to be effective in increasing the volume of starch-gluten loaves, but pentosans from other sources can produce similar effects, the most effective being those with the main chain carrying large substituent groups. However, one surprising fact to be reported is the inhibition of yeast fermentation by the presence of 3 p.p.m. of chitosan (partially deacetylated chitin). Pentosan degradation investigations using "snail juice enzymes" have shown that, while loss of baking quality can result from the action of pentosanases, the neutralizing or improving effect of oxidizing agents such as potassium bromate cannot be explained by their ability to promote gelling of pentosans.

### Soils of the Middle Teign Valley District of Devon

THE Soil Survey of Great Britain normally prepares memoirs to accompany soil maps; it has now started to publish Bulletins dealing with investigations of special interest. The first to be issued is concerned with a district of eight parishes around Dunsford, of total area 40 square miles, of which the southern half comprises the Teign Valley between Great Haldon and Dartmoor (Bulletin No. 1: *Soils of the Middle Teign Valley District of Devon*. By B. Clayden. Pp. vii+111+map. Harpenden: Rothamsted Experimental Station, 1964. 25s. net).

Small mixed farms engaged in milk production predominate and the soil is an important factor in the economy, so that a soil survey was undertaken to assist the Nuffield Farm Project sponsored by the Nuffield Foundation and the Ministry of Agriculture, Fisheries and Food. The Bulletin gives a detailed account of the physical features, climate, geology and soil parent materials. Although the district as a whole is characterized by high precipitation and mild winters, local conditions give rise to wide variability from the average rainfall and temperatures. The methods of mapping and soil classification are described and coupled with numerous analytical data from representative profiles on Culm shales and granite, from brown earths and from gley soils. There are practically no calcareous soils, and soils of high base status are confined to those developed on the diabase, on red loamy head and on base-rich alluvium. The non-calcareous Culm rocks give markedly acid soils. A chapter on the history of agriculture in the area leads on to present-day farm practices, with statistics of farm sizes and enterprises and some discussion of the relationships between productivity and soil properties. There is a bibliography of scientific papers and an index.

### Spring-tails of the World

EVER since Sir John Lubbock, in his Ray Society Monograph of 1873, recognized that the Collembola (for which he proposed this name) should be regarded as a separate order of apterygote insects, the group has attracted enthusiastic devotees. They form a compact yet diverse group of insects, comprising three sub-orders, some sixteen families, and about 1,500 described species. Comparatively little is known about their ecology; but the vast numbers present in the soil suggest that they must be of the utmost importance in soil microbiology. Even less is known of their physiology. Dr. J. T. Salmon of the Victoria University of Wellington, New Zealand, a recognized authority on the group, has published a two-volume *Index to the Collembola* (Royal Society of New Zealand. Bulletin No. 7: Salmon. Vol. 1: Pp. 1-144; Vol. 2: Pp. 145-644. Wellington: Royal Society of New Zealand, 1964). This impressive work records the known genera and species of the Collembola of the world, their synonyms, type repositories, geographical distribution, taxonomic descriptions, morphology, embryology and ecology up to the end of 1962, and includes a key to genera throughout the world. The second volume consists of classified references to each species. There are something like 36,000 such references, each with an indication of the nature of the information it contains. This should prove to be the standard reference work to the 'spring-tails' for many years to come.

### Enteric Infections in Children

EVERYONE concerned with child welfare will be interested in the report recently issued by the World Health Organization Expert Committee, entitled *Enteric Infections* (World Health Organization Technical Report Series, No. 288, obtainable in the United Kingdom from H.M.S.O., 5s.). It is also published in French and Spanish. In many developing countries enteric infections are the most important causes of illness and death among children, and the report gives statistics of the illness and mortality due to them. In countries in which they are endemic they cause an infant mortality of more than 100 per 1,000 live births. A cardinal symptom of these diseases is diarrhoea, and the term enteric infections includes a variety of clinical syndromes of various aetiology. The most important causes are *Escherichia coli* and species of *Salmonella* and *Shigella*. Valuable sections of the report discuss the factors which contribute to the occurrence of these infections and their control. Many deaths due to them could be avoided by the application of knowledge already available, but the report discusses the diagnosis of the infections, the

further research needed and the requirements for control, including health education, environmental sanitation, control of flies, water supplies, child care—especially of ill-nourished children—and the expansion of health centres.

### Postgraduate Agricultural Studentships and Awards

A LIMITED number of postgraduate studentships are to be awarded by the Ministry of Agriculture, Fisheries and Food, and the Department of Agriculture and Fisheries for Scotland, for the academic year beginning October 1. These will cover the various branches of husbandry (including horticulture), farm management, agricultural or horticultural economics, agricultural or horticultural statistics, marketing, agricultural and dairy engineering (including farm mechanization), rural estate management and agricultural science. Applicants normally resident in England, Wales and Northern Ireland can obtain further information and forms of application from the Ministry of Agriculture, Fisheries and Food, Room 231A, Great Westminster House, Horseferry Road, London, S.W.1. Applicants normally resident in Scotland should apply to the Department of Agriculture and Fisheries for Scotland, Room 53, St. Andrew's House, Edinburgh, 1. The closing date for receipt of completed application forms is February 28.

Postgraduate awards are also offered by the Agricultural Research Council, Cunard Building, 15 Regent Street, London, S.W.1, for training in research. These are open to honours graduates in science or those holding a veterinary qualification, and to honours graduates in agriculture or horticulture who have shown a special interest in one of the basic sciences. Applications for awards in veterinary science should also be made to the Agricultural Research Council.

Awards are also available to postgraduate and post-doctoral students of agricultural science under the NATO Science Studentship and Fellowship Programme, which is intended to encourage the exchange of students between member countries in NATO. The scheme is administered for United Kingdom students by the Department of Scientific and Industrial Research, State House, High Holborn, London, W.C.1, to whom application should be made by March 1.

### Lady Tata International Grants, Scholarships and Fellowships for Research on Leukaemia and Allied Conditions

THE Trustees of the Lady Tata Memorial Trust invite applications for fellowships, scholarships and grants for research on leukaemia, in the academic year beginning October 1. In view of the affinity between leukaemia and other forms of neoplastic disease, candidates with programmes of research on any aspect of malignant disease which may throw light on problems of leukaemia will be eligible for consideration, and especially those studying leukaemogenic viruses in mammals, the epidemiology and natural history of leukaemia, and the immunogenetic aspects. The awards offered by the Trust are open to suitably qualified investigators of any nationality, working either in their own institutions or in other centres abroad. Applications must be submitted before March 31, and awards will be announced by the Trustees in June. Further information and forms of application can be obtained by writing to the secretary of the (European) Scientific Advisory Committee, Lady Tata Memorial Trust, Chester Beatty Research Institute, Fulham Road, London, S.W.3.

### The Leopoldina German Academy of Sciences: Elections

THE Deutsche Akademie der Naturforscher Leopoldina, Halle, recently elected the following new members in the sections indicated: *Mathematics*, Prof. H. Heinrich

(Dresden); *Physics*, Prof. S. Tomonaga (Tokyo); *Geophysics*, Prof. G. Fanslau (Potsdam) and Prof. C. Junge (Mainz); *Chemistry*, Prof. R. Huisgen (Munich), Prof. T. Wieland (Frankfurt/M) and Prof. H. M. Pamir (Ankara); *Physical Chemistry*, Dr. M. Eigen (Göttingen); *Mineralogy*, Prof. F. Machatschki (Vienna); *General Biology*, Prof. H. Bauer (Tübingen), Prof. A. Gierer (Tübingen) and Dr. H. G. Wittmann (Tübingen); *Botany*, Prof. A. Lang (East Lansing, Michigan); *Anatomy*, Prof. J. Szentágothai (Budapest); *Physiological Chemistry*, Dr. A. Kornberg (Palo Alto, California) and Prof. J. Monod (Paris); *Internal Medicine*, Prof. H. Schulten (Cologne) and Prof. J. G. Waldenström (Malmö); *Dermatology*, Prof. S. Jabłońska (Warsaw), Prof. A. Wiedmann (Vienna) and Prof. W. Kalkoff (Freiburg/Br.), *History of Natural Science and Medicine*, Prof. G. R. A. Uschmann (Jena).

#### University News:

#### Churchill College

DR. J. R. KILLIAN, jun., chairman of the board of the Massachusetts Institute of Technology, has been elected into an overseas fellowship (Title F) at Churchill College.

#### London

PROF. R. H. S. THOMPSON, professor of chemical pathology at Guy's Hospital Medical School, has been appointed to the Courtauld chair of biochemistry tenable at Middlesex Hospital Medical School. Dr. D. Rogers, reader in chemical crystallography at the Imperial College of Science and Technology, has been appointed to the chair of chemical crystallography tenable at that College. Dr. T. S. West, reader in analytical chemistry at the Imperial College of Science and Technology, has been appointed to the chair of analytical chemistry tenable at that College. Mr. J. H. Kirk, under-secretary, Ministry of Agriculture, Fisheries and Food, has been appointed to the chair of marketing with special reference to horticulture tenable at Wye College.

#### Southampton

BUILDING work costing £2,250,000 is at present in progress. New buildings in course of erection include an eleven-storey Mathematics Building, a four-storey Students' Union Building, a single four-storey building to accommodate the Departments of Botany and Geography, a five-storey Physics Building and a smaller building to accommodate the new Department of Oceanography. Additional residential accommodation for 350 students is also being built. A Department of Oceanography has been established as a separate department in the Faculty of Science. The first head of the Department will be Prof. J. E. G. Rayment, who has transferred from the chair of zoology in the University. Apart from biological and chemical oceanography, which is being undertaken by the new Department, there will be an early development of physical oceanography. At present the new Department is entirely postgraduate and trains students for an M.Sc. course in oceanography as well as accepting students for research. Dr. L. Brent, of the Medical Research Institute, has been appointed to succeed Prof. Rayment as professor of zoology and head of the Department of Zoology.

#### Announcements

SIR GEOFFREY TAYLOR was awarded the James Watt International Gold Medal of the Institution of Mechanical Engineers on January 27, in recognition of his long and distinguished career and his many contributions to mechanical engineering.

PROF. R. G. W. NORRISH, of the University of Cambridge, delivered the twenty-fourth Faraday Memorial Lecture of the Chemical Society at the Royal Institution on January 14, and was afterwards presented with the Faraday Medal of the Society.

THE James Clayton Prize of the Institution of Mechanical Engineers, worth £1,700, has been awarded equally to Mr. F. H. Towler (Towler Brothers (Patents), Ltd.) for his work on the design, development and manufacture of heavy hydraulic equipment and related controls, and to Dr. A. E. W. Austen (C.A.V., Ltd.) for his research on the development of diesel engines and related equipment.

Dr. E. Ambler, Dr. R. Hayward, Dr. D. Hoppes and Dr. R. Hudson are to receive the 1964 Samuel Wesley Stratton Award of the U.S. National Bureau of Standards, for their work in demonstrating that the quantum mechanical law of parity conservation does not hold in weak interactions.

THE seventeenth technical exhibition of the Oil and Colour Chemists' Association will be held in London during March 22-26. Further information can be obtained from the General Secretary, Oil and Colour Chemists' Association, Wax Chandlers' Hall, Gresham Street, London, E.C.2.

A MEETING of the Oxford local section of the Institute of Metals will be held in Oxford on March 16. At the meeting, a lecture on "How and Why of Strong Magnetic Fields" will be delivered by Dr. N. Kurti. Further information can be obtained from the Institute of Metals, 17 Belgrave Square, London, S.W.1.

THE sixteenth Pittsburgh conference on "Analytical Chemistry and Applied Spectroscopy" and Exposition of Modern Laboratory Equipment will be held in Pittsburgh during February 28-March 5. Further information can be obtained from the programme chairman, W. G. Fateley, Mellon Institute, 4400 Fifth Avenue, Pittsburgh, Pennsylvania 15213.

THE second symposium on "Progress in Biochemistry and Therapeutics" of the Carl Neuberg Society for International Scientific Relations will be held in New York City during March 23-24. The main topics of the symposium will be drugs, enzymes and diseases. Further information can be obtained from Mr. I. Greenberg, Carl Neuberg Society, 600 Lafayette Avenue, Brooklyn, N.Y. 11216.

A SERIES of lectures on "Railways Research", arranged through the courtesy of British Railways, will be held at the Imperial College of Science and Technology during the first half of 1965. The programme will include the following lectures: the application of automation to railways (March 1); riding of railway vehicles (March 22); communication with moving trains (May 10); fatigue problems in railway engineering (May 31); fuel cells for traction (June 14). Further information can be obtained from the Registrar, Imperial College of Science and Technology, London, S.W.7.

A CONGRESS on the "Protection of Tropical Crops", sponsored by the regional Chamber of Commerce and Industries, will be held in Marseilles during March 23-26. The programme will include sessions on: organization and methods of plant protection in the tropics; pesticides (mode of action, conditions of application, methods for testing in the field, equipment developed for their application); protection of stored products; protection of timber; control of birds, rats, locusts, root diseases, virus diseases; biological control. Further information can be obtained from Dr. G. Bouriquet, 45 bis avenue de la Belle Gabrielle, Nogent sur Marne, Seine.

CORRIGENDUM. The Editor has been informed by Dr. R. Kluthe *et al.* that in the communication entitled "Quantitative Estimation of Human Serum Haptoglobins by an Immunological Method" (*Nature*, 205, 93; 1965) the block for Fig. 1 and its key (but not legend) belong to Fig. 2, while the block for Fig. 2 and its key belong to Fig. 1.

## THE NATURE CONSERVANCY

ABOUT one-third of the fifteenth annual report of the Nature Conservancy\*, covering the year ended September 30, 1964, is again occupied by brief accounts of scientific research in progress, but some further scientific work is described in the account of the Scientific Advisory Services, for example, the work on grey seals and fisheries (on which the Consultative Committee on Grey Seals and Fisheries arranged a scientific symposium on September 9, 1964). Reference is also made in that section of the report to the establishment of a Biological Records Centre at Monks Wood Experimental Station, using as a nucleus the Botanical Society's records and data-processing machinery. (The work of the Scientific Advisory Services and the conservation work are considered on p. 631 of this issue of *Nature*.)

During the year, £104,297 was spent on research, studentships, training and special surveys, and £81,073 of this went to grants for research, studentships and training. In all, £63,027 was spent on research grants, including 12 new grants totalling £27,282, one of which (£9,500) went to the Wildfowl Trust towards the building and equipping of one floor of the Trust's new research centre at Slimbridge. Renewed grants included an interim £9,500 to the British Trust for Ornithology for investigations on bird populations and migration.

The Merlewood Research Station and the Moor House Field Station are now closely integrated and there is increasing collaboration with universities. The woodland botanists, who are mainly concerned with investigations on low-level oak woodlands, are now examining the nutrition of trees at 1,800 ft. at Moor House, and the investigations will provide important information on the possibilities of growing trees, not necessarily for the production of economic timber, but as ecological tools for the proper utilization of hill-land. Much attention is being directed to the circulation of mineral nutrients within the woodland and moorland ecosystem, including an examination of the rate at which nitrogen-fixing organisms can supplement the input by rain and so restore the major depletion of nitrogen—some 70 per cent when moorland vegetation is destroyed by burning.

Research at Furzebrook is concentrated on populations and physiography, including hydrology. The distribution survey of the Dorset heath (*Erica ciliaris*) has been completed and further sites selected for investigation. A stratigraphical and ecological examination of the valley bogs in Dorset has been started, including a detailed survey at Morden Bog National Nature Reserve, where pitfall trapping of spiders continued and was started at Studland Heath National Nature Reserve. A detailed historical investigation of the changing *Spartina* marsh pattern since the first appearance of the grass in Poole Harbour in 1900 has been completed. A detailed recent survey puts the area in Poole Harbour at about 1,700 acres, and it appears possible that the growth limits of marsh plants may be sensitive indicators of small-scale recent changes in sea-level. Investigations have also been made on the physiography, tidal submergence and chlorinity of the salt marshes in Poole Harbour, and coastal research has been continued at Bridgwater Bay, Orfordness, Braunton Burrows and Dawlish Warren, including examination of the chronology of their evolution. A survey of water balance programmes was concentrated on the peat uplands of the west and north and,

to a lesser extent, on the Woodwalton Fen area of Huntingdonshire.

At Monks Wood Experimental Station, work on moles (*Talpa europaea*) commenced, particularly in Monks Wood and Woodwalton Fen. Detailed measurements of seedling growth were made in the experimental blocks at Yarnar Wood, Monks Wood, Wychwood, Holme Fen and Castor Hanglands National Nature Reserves and the effects of various treatments are being assessed. Investigations by live trapping of populations of the bank vole (*Clethrionomys glareolus*) and wood mouse (*Apodemus sylvaticus*) continued, and the programme of sampling the invertebrate fauna of two contrasting grass-heaths in the East Anglian Breckland has been completed. The examination of the succession of aquatic invertebrates in a dyke at Woodwalton Fen was continued, as well as those of the changes in vegetation of a south-facing slope at Old Winchester Hill as a result of sheep-grazing, and of the effect of sheep-grazing on the floristic composition of chalk grassland on the Barton Hills, Bedfordshire.

New work in the Toxic Chemicals and Wild Life Section includes examinations of the arthropod fauna of hawthorn hedges in relation to the presence of associated herb species; of the plants and insects of roadside verges, with the view of providing a scientific basis for advice on the conservation aspect of roadside maintenance; of the invasion of fields by selected weed species from hedges; and of the rate of destruction of hedges. Investigations on the distribution and size of organochlorine insecticide residues in mammals, birds, birds' eggs and invertebrates have been greatly helped by a gas chromatographic apparatus.

In May 1964 the research programme on red deer on Rhum was extended to cover the feeding ecology of the animal and thus establish a link with the investigation of vegetation production. The survey for the vegetation map of Rhum has been completed and it will now be possible to estimate the approximate acreages of the plant communities grazed by the red deer. Censuses were again made throughout Orkney by the Grey Seals Research Officer, and examinations were made at breeding colonies in Colonsay, on islands in the Sound of Harris and in Orkney and Shetland. The substantial winter mortality of adult Soay sheep on Hirta and of the subsequent lambing was investigated in March–May 1964. An investigation of the ecology of birch in the Highlands has been started, while further improvements have been made in the techniques of collecting and extracting the seeds of trees and shrubs for use on reserves. Investigations of red grouse (*Lagopus lagopus scoticus*) at Blackhall and Kerloch, Kincardineshire, have concentrated on behaviour and nutrition in relation to a long-term population examination. At the Speyside Research Station much of the research of the Climatological Section concerns the climatological aspects of productivity investigations, particularly the water balance and changes in air humidity. Research at the Bangor Research Station continues to be concerned with investigations in Snowdonia on the influence of variations in local climate and geology on soils, vegetation (particularly grasslands and related arctic-alpine communities) and biological productivity. An X-ray fluorescence spectrographic method has been developed for the rapid analysis of the major elements in powdered rocks. Earlier studies of sheep population densities and their growth have been extended to an investigation of the increment of plant 'dry matter' and energy by different plant communities in summer.

\* Report of the Nature Conservancy for the year ended September 30, 1964. Pp. vii + 173 + 10 plates. (London: H.M.S.O., 1964.) 13s. net.

## THE NATIONAL PARKS COMMISSION

THE fifteenth annual report of the National Parks Commission\* covers the year ending September 30, 1964, and, like the present report of the Nature Conservancy, it makes special reference to the study conference, "The Countryside in 1970", held in November 1963. It also comments on the acute problem presented by coastal preservation and development and, like the Conservancy, welcomes the action of the National Trust in initiating 'Enterprise Neptune', the object of which is the conservation of selected stretches of coast line in co-operation with local planning authorities. On water supply problems the Commission regards with grave misgiving any scheme which would begin to abstract water from Ullswater, and adds that any proposals to flood the Winster Valley would be resisted most strongly. During the year under review new orders designating the forest of Bowland and Chichester harbour as areas of outstanding natural beauty were confirmed, but decisions are awaited regarding the Chilterns and the Solway coast areas. The Pennine Way long-distance footpath has now been completed, and provides a strenuous high-level walk from Edale, in the Peak District National Park, to the Cheviots and the Scottish border, passing through two other National Parks, the Yorkshire Dales and Northumberland. Special efforts have been made to assist local authorities in resolving difficulties, and in negotiating outstanding footpath agreements, in their areas regarding the Offa's Dyke path, but coastal erosion still presents difficulties in maintaining the south-west peninsular coast footpath. The definitive maps for the south Devon coastal area are now complete and should simplify consideration of outstanding public rights of way on the Devon south coast path, while some progress is reported with regard to the South Downs way.

The report includes brief accounts of progress during the year with each of the 10 national parks, but development questions continue to present the Commission with its main problems, and some 410 proposals for development affecting landscape beauty in national parks were referred to the Commission during the year. The Commission notes that the South Wales Electricity Board

proposed to carry out, during the year 1964-65, the first stages of an operation involving the expenditure of £50,000, primarily to improve visual amenities in the electricity distribution network area of South Wales. Strenuous efforts have been made by the two Yorkshire National Parks planning authorities, with the support of the Commission, to effect a change in the policy of the North East Electricity Board with regard to overhead supply lines. With regard to the 4,000-kV line in the southern counties, for which the Commission suggested alternative routes, the Commission has asked that, should the Minister of Power decide that the case for consent to the Electricity Board's proposed route is overwhelming, a definite time limit should be set for the removal of the lines, the towers and the bases, and that the period should be as short as possible. The Commission has also discussed with the Central Electricity Generating Board the project for a pump storage scheme in North Devon, with regard to the possible effects on the coast, including the approaches from land and sea and the recreational potential which the upper reservoir or reservoirs may have. The Minister of Power has again been approached with regard to the placing underground of the electricity lines in Martindale in the Lake District National Park.

Representations were made to the Minister of Transport regarding the proposal to withdraw passenger services from the Taunton to Barnstaple line, but without effect. The Minister of Transport, however, has decided to continue passenger services on the line from Llandudno junction to Blaenau Ffestiniog line, closure of which was also opposed by the Board. The Commission particularly welcomes the Minister of Transport's statement to the Ramblers Association regarding traffic restrictions in the remote countryside, particularly his view that he would expect the Highway Authorities to take into account the views of the National Park Planning Authorities in submitting improvement schemes to him for grant purposes. The Minister also said that he was ready to consider orders made on grounds of amenity so long as provision was made for carrying on the normal life of the district without imposing unreasonable burdens. Further reference to this question and also to the Commission's present views regarding recreational facilities in National Parks is made on p. 632 of this issue of *Nature*.

\* National Parks and Access to the Countryside Act, 1949. Fifteenth Report of the National Parks Commission for the year ended September 30, 1964. Pp. vii + 89 + 8 plates. (London: H.M.S.O., 1964.) 8s. net.

NUFFIELD FOUNDATION SCIENCE TEACHING PROJECT:  
PROGRESS REPORT

THE progress report of the Nuffield Foundation Science Teaching Project\* appeared towards the end of 1964. The work is now being extended to cover the teaching of science to children of all ages in most types of schools. Work began in 1961 on the design of courses leading to O-level examinations in physics, chemistry and biology. Programmes for the improvement of science and mathematics teaching have already been announced. The progress report now published describes some of the plans being made to design science courses for sixth forms and for 'Newsom' children (the less able half of the school population) in the 13-16 year range.

Since the preparation of the report, the Nuffield Trustees have allocated a further £115,000 to science teaching, chiefly to support A-level biology. So far

£550,000 has been set aside for science teaching, but this figure does not cover work in the physical sciences in the sixth form and the proposed programme for the 'Newsom' children. During the next year a sum of a quarter of a million pounds will have to be spent on the first printing of the teachers' guides and pupils' books due to be published in April 1966.

A hundred and fifty British secondary schools and a total of three thousand children in more than two hundred classrooms are being used in the controlled testing of the O-level courses. This is most necessary: far too many text-books are the results of their authors' attempts to dilute or re-present material from the standard works. Large groups of children will have to be the yard-sticks by which teaching material is validated. This absorbs time and money and may prove to be inhibiting to the over-facile writer of school text-books, but it is the only permissible way for the future.

\* The Nuffield Foundation Science Teaching Project. Progress Report, October, 1964. Pp. 81. (London: Longmans, Green and Co., Ltd., and Penguin Books. Published for the Nuffield Foundation.)

Another guiding principle is that science should be made intelligible and enjoyable, even in the work of the public examinations. Experimental work is a conspicuous part of the Nuffield courses. Many local authorities have helped to give the courses a fair trial by spending several hundreds of pounds a school on new scientific equipment.

Alternative O-level examinations for children using Nuffield courses in physics, chemistry and biology are to be provided by the public examinations in the years ahead, so that children engaged in the testing of new courses will not be hampered. A hundred titles in the first printing of about three million books will appear in spring

1966 and, in addition, there are films, film loops and other special items of equipment developed during the programme, and other visual aids.

The future of the O-level courses is said in the report to depend on the extent to which practising teachers will be helped to make the best use of the new methods. No charitable organization can be responsible for the work in the future, and the Department of Education and the local education authorities will have to give major support. The report outlines future developments, including a project to teach general science in the 11-13 age range.

W. L. SUMNER

## ANTIMICROBIAL AGENTS AND CHEMOTHERAPY

VARIOUS aspects of antimicrobial agents, infectious diseases, microbiology, and chemotherapy were discussed in the 162 papers presented at the fourth Interscience Conference on Antimicrobial Agents and Chemotherapy. This meeting was held in New York during October 26-28, 1964, under the sponsorship of the American Society for Microbiology and organized with the co-operation of the Infectious Diseases Society of America. Dr. N. Bohonos (Lederle Laboratories) was chairman of the conference. 1,045 scientists attended this meeting, including representatives from eighteen countries in all.

The three-day conference opened with an address by Dr. M. Finland (retiring president of the Infectious Diseases Society) on problems in the clinical investigation of new drugs. The role of the U.S. Food and Drug Administration and other regulatory agencies was reviewed, and the necessity of allowing the investigator to exercise some initiative and responsibility was mentioned. The John Scott Award for meritorious scientific achievement was presented at this session by the City of Philadelphia (Pennsylvania) to Prof. J. C. Sheehan (Massachusetts Institute of Technology) for his research leading to the preparation of the 'semi-synthetic penicillins'.

Among the features of the 1964 meeting were four symposia. Prof. M. Hamburger chaired the first, which dealt with "Penicillins and Cephalosporins" and included reviews of the clinical status of cephalothin (by W. M. Kirby), ampicillin (by S. Ross), oxacillin and methicillin (by H. Simon), and nafcillin (by C. M. Martin). P. B. Bunn described his experience with penicillin allergy and emphasized the apparent lack of strong sensitivity to ampicillin of patients allergic to benzylpenicillin (penicillin G). It was obvious that some of these newer semi-synthetic penicillins were as clinically useful in treatment of certain Gram-negative infections as some of the other antibiotics, for example, chloramphenicol, polymyxin, and colistin. However, as Prof. Simon pointed out, we do not as yet have a 'panaceamycin' for all infections. M. R. Pollock, (National Institute for Medical Research, London) summarized his investigations of the  $\beta$ -lactamases of bacteria. These enzymes, which inactivate both penicillins and cephalosporins under laboratory conditions, may not be entirely responsible for the penicillin resistance noted in certain bacterial cultures.

Dr. H. C. Reilly (Sloan Kettering Institute) presided over a symposium on "Antineoplastic Antibiotics". S. A. Schepartz reviewed the programme of the Cancer Chemotherapy National Screening Center, in which searches are being made for anti-neoplastic antibiotics from fermentation processes. Thirty materials (isolated from more than 115,000 'crude' broths screened) have been considered for clinical evaluation, but none has shown 'great promise'. An investigation of the incidence of anti-neoplastic activity among antibiotics that act as inducers of lyso-genic bacteria was discussed by K. E. Price (Bristol Laboratories), who found a high correlation between anti-neoplastic activity and induction of lambda phage

in *E. coli* W1709. J. J. Fox (Sloan Kettering Institute) reported that gougerotin contains sarcosyl-D-serine in acyl-amino linkage to 4-amino-4-deoxy-hexuronic acid amide, and concluded that the structure proposed earlier for this antibiotic was in error. He pointed out that all known pyrimidine nucleoside antibiotics (elaborated by *Streptomyces* species) contain cytosine and 4-amino-hexose moieties. A. Bloch and C. A. Nichol (Roswell Park Memorial Institute) commented on the nucleoside antibiotics related to adenosine with special reference to their effects on adenosine phosphorylase, deaminase, and kinase. R. D. Sullivan (Lahey Clinic Foundation, Boston) pointed out that doses 2-2.5 times as great as those tolerated by single daily injection were well tolerated by prolonged intravenous infusion of actinomycin D, streptonigrin, and mitomycin C, and went on to review recent progress in the use of these antibiotics in cancer chemotherapy.

"The Future of Antiviral Drugs" was the subject of a session convened by E. C. Herrmann, jun. (The Mayo Clinic). F. M. Schabel (Southern Research Institute) and I. S. Johnson (Eli Lilly and Co.) discussed the theoretical basis for examining antiviral chemotherapy and problems in the detection of antiviral antibiotics. The successes in viral treatment following the use of 5-iodo-2'-deoxyuridine, cytosine, and 5-azaorotic acid were reviewed by P. Calabresi (Yale University); and R. L. Thompson (National Institutes of Health, Bethesda) summarized the tests with *N*-methylisatin- $\beta$ -thiosemicarbazone and other thiosemicarbazones. The promising laboratory and clinical results with 1-adamantanamine hydrochloride were reviewed by C. E. Hoffman (E. I. DuPont de Nemours and Co.).

"The Usefulness of Synthetic Antimicrobials" was the subject of a symposium chaired by Dr. D. Lehr (New York Medical College). Dr. J. Alban (Stanford University), E. H. Kass (Harvard University), J. P. Colmore (Oklahoma Medical Center), and D. F. McDonald (University of Rochester) gave information on the present status of the sulphonamides, nitrofurantoin, and nalidixic acid.

Among the new antibiotics mentioned at the Conference were:

(1) The *S*-ethyl homologue of lincomycin and *N*-demethyl analogue of lincomycin formed by adding DL-ethionine and  $\alpha$ -methylthiolincosamide, respectively, to lincomycin-producing fermentations according to Argoudelis *et al.* (The Upjohn Co.). (2) Everninomicin, a new antibiotic complex derived from *Micromonospora carbonacea* which inhibits Gram-positive bacteria and PPLO, as shown by Weinstein *et al.* (Schering Corporation). (3) Almarcetin, a new polypeptide antibiotic which may be useful against phytopathogens, according to Bachler *et al.* (Northern Regional Research Laboratory, U.S. Department of Agriculture). (4) Monicamycin, an acidic heptaene antifungal agent isolated by Gupta (Regional Research Laboratory, Jammu-Tawi, India). (5) Rubiflavin, a toxic anti-tumour antibiotic described by Aszalos *et al.* (Squibb Institute for Medical Research). (6) U-13714, a

toxic antiviral agent isolated by Vavra *et al.* (The Upjohn Co.) from *Streptomyces canarius*. (7) LL-AP191, a xanthomycin-type antibiotic inhibiting both Gram-positive and Gram-negative bacteria according to H. A. Whaley *et al.* (Lederle Laboratories). (8) LL-A1471E, a macrolide antibiotic inhibiting Gram-positive bacteria, reported by M. P. Kunstmann *et al.* (Lederle Laboratories). (9) U-11092, an antibiotic inhibiting Gram-positive bacteria *in vivo* when given either *per os* or subcutaneously, according to B. K. Bhuyan *et al.* (The Upjohn Co.). (10) Enteromycin (seligocidin) from a streptozotocin-producing fermentation, as reported by R. R. Herr *et al.* (The Upjohn Co.). (11) Enteromycin carboxamide isolated by S. DeVoe *et al.* (Lederle Laboratories) from a streptomycete fermentation.

A wide variety of topics were discussed in the sessions concerned with clinical problems and treatment in humans: (1) Animal infections examinations which were pertinent to understanding host resistance and drug action, which included: pneumococcal infections in splenectomized monkeys; prophylaxis of aerogenic Rocky Mountain spotted fever in monkeys; experimental histoplasmosis capsulitis endocarditis; coxsackie A-9 infection in adult mice treated with steroids and in mice with forced exercise; penicillin toxicity in guinea-pigs as related to changes in microbial flora; and renal infection with enterococcal protoplasts (in rats). (2) Clinical investigations concerned several chronic conditions, which included: fungal diseases in reticuloendothelial malignancies; infection in volunteers with penicillin-resistant gonococci; staphylococcal carriers; chronic bronchitis and pulmonary disease; retreatment of tuberculosis, *Salmonella* carriers, urinary tract infections and pathogenic studies in Gram-negative rod infections. (3) Studies of antibody responses, which included gonococcal and meningococcal infections, herpes simplex disease and staphylococcal states.

A series of papers on experimental infections covered: (1) *Mycobacterium fortuitum* in mice as a screen for tuberculosis; (2) hamycin in experimental mycoses in mice; (3) a standardized *Leptospira pomona* infection in hamsters; (4) experimental localized *Pseudomonas* infection (keratitis) in rabbits; (5) septicæmic anthrax in rhesus monkeys; (6) the use of sulphonamides in murine leprosy.

The modes of action of a number of antibiotics were mentioned, including D-cycloserine, vernamycin A, vancomycin, mitomycin C, porfomycin and streptonigrin. Among the synthetic antimicrobial agents reported for the first time were an antifungal agent, tolnaftate (O-2-naphthyl-m,N-dimethylthiocarbamate), 1-(5-nitrofurfurylideneamino)-2-imidazolidinone, and 4(5-nitro-2-furyl)-2-(3-pyridyl)thiazole.

Most of the papers presented at the Conference will appear in *Antimicrobial Agents and Chemotherapy, 1964*, which will be published by the American Society for Microbiology (Ann Arbor, Michigan) in April 1965. The *Proceedings* will be distributed to all registrants at the meeting, and will be available from the American Society for Microbiology or from Messrs. H. K. Lewis, London.

Plans for the 1965 conference are already under way. This meeting will be combined with the fourth International Congress of Chemotherapy and will be jointly sponsored by the American Society for Microbiology and the International Society for Chemotherapy. Programmes on infectious diseases will be organized with the co-operation of the Infectious Diseases Society of America. The sessions will be held in the Shoreham Hotel, Washington, during October 17–21. Dr. G. M. Savage (The Upjohn Co.) is general chairman, and enquiries concerning arrangements and participation should be sent to Mr. R. W. Sarber, Executive Secretary, American Society for Microbiology, 115 Huron View Boulevard, Ann Arbor, Michigan. D. PERLMAN

## METEOROLOGY AND LOCUST MIGRATIONS

A TECHNICAL Note recently published by the World Meteorological Organization covers a great deal of ground in the relationship between meteorology and the movement of locust populations\*. Work on locust problems started in 1929 under Prof. B. P. Uvarov at what has now become the Anti-Locust Research Centre, and Dr. R. C. Rainey, who was a glider before the Second World War, a wartime meteorologist, and again an entomologist working with the Centre after the War, is uniquely qualified to write on meteorological aspects of locust populations. The note is very well produced, as are most of the World Meteorological Office Technical Note series, with 24 figures and three instructive photographs of locusts in flight, which hint at the problem—the immensity of which is realized by figures such as a swarm density per square kilometre of about  $5 \times 10^7$  locusts, weighing  $10^5$  kilograms and eating their own weight of vegetation each day. Swarms can cover hundreds or even thousands of square kilometres. As an example of financial loss, Morocco's loss in the year 1954–55 was assessed at about 13 million dollars; and Morocco was only one of 23 countries which suffered losses in that year.

The main emphasis is on the detailed survey for the year May 1954–May 1955, during which the Anti-Locust Research Centre collaborated closely with the World Meteorological Organization mission in East Africa headed

by C. I. H. Aspliden, part author of Chapter 3. Considerable flying, both spotter and spraying, was undertaken, and swarm movements could be followed with far greater certainty than in any earlier work. Identifiable swarms flew for very variable distances up to 3,500 km, with a maximum followed flight time of around two months. After a short introduction outlining the life cycle of the locust, meso-scale consideration is given to the individual swarm behaviour, and the general movement downwind is brought out clearly. Earlier investigations sometimes found variation between winds and swarm movements; this was presumably largely a question of difficulties of reliable assessment by ground observers, who could be unduly influenced by individual locust movements. Even in light winds, swarms nearly always moved more slowly than the surrounding air, although individual locusts may fly more quickly. This is caused by a sort of rolling effect, where the swarm 'front' rolls forward, with individual locusts spending some time on the ground if the swarm is low; flight level varied widely, however, with swarms at many thousands of feet on occasions. This agreement between wind and swarm movement is very valuable, as, for example, arrival of swarms in a new area can be foreseen.

The special survey year is documented with excellent monthly charts showing the locust distribution over the whole area from India westwards to Morocco, and including Central Africa; the development stage of the locust (whether hoppers, etc.) is also brought out. Each area is briefly discussed, with an analysis of locust behaviour during the year.

\* World Meteorological Organization and Anti-Locust Research Centre. *Meteorology and the Migration of Desert Locusts: Applications of Synoptic Meteorology in Locust Control*. By R. C. Rainey. Pp. 115. (W.M.O. Technical Note No. 54—No. 138. TP. 64. Anti-Locust Memoir No. 7.) (Geneva: World Meteorological Organization; London: Anti-Locust Research Centre, 1964.) 25 Sw. francs; 42s.

Rainey puts forward the view that, broadly speaking, the locust populations are at their greatest to the south side of the Intertropical Convergence Zone (ICZ) and that frequently swarms of locusts follow by a day or two the northward moving ICZ. This is logical, since semi-tropical locusts must eventually get carried by northerly moving airstreams towards a convergence zone.

Locusts are essentially hot-climate insects, and the mostly light wind régimes which obtain in the semi-tropics do not give much opportunity for their movement outside the tropics. However, it does happen from time to time that an active depression tracking south of the Mediterranean carries the locusts bodily in the warm sector to areas north of the African coast. The classic migration example is quoted (with a trajectory map) of the locusts which reached the Isles of Scilly and Southern Ireland in October 1954—the first live locusts known to reach the British Isles since 1869. This type of trajectory technique has been applied more recently to moth migrations and spore movement with very similar types of track.

The pages of recommendations in Chapter 4 underline the importance of the type of collaboration found in meteorological networks and the inestimable value of aircraft both for spotting and for spraying. The control of locust movement by low-level winds is brought out, and also the importance of the ICZ. About the only point with which one might quarrel is the suggestion of a relationship between sunspot activity and the fluctuation of locust infestations which, viewed from a meteorological point of view, seems doubtful. Some of the diagrams such as those showing the effects of South Mediterranean depressions are not too happy; they have been stylized and appear distinctly confusing to a meteorologist.

There is no doubt of the value of the Note to anyone interested in either locust control problems or any insect migrations in general, and it is good to see such happy collaboration between such bodies as the Anti-Locust Research Centre and the World Meteorological Organization.

## PROTECTION AGAINST IONIZING RADIATIONS

THE informative and well-written *Protection Against Ionizing Radiations*\*, issued by the World Health Organization, concerns legislation on protection against the use of ionizing radiations. Apart from an introductory chapter outlining the need for control and making a general survey of existing legislation, the book is principally a detailed account of the legislation in force in 26 different countries. On these grounds it cannot fail to be of interest and a constant source of reference to all those concerned with radiological health and safety.

The scope of legislation varies widely from country to country, revealing many interesting aspects of their developing use of ionizing radiations and national characteristics. In some countries, it is extremely detailed, covering almost every aspect of protection, while in others it is quite general in character and greater reliance is placed on the voluntary action of users to maintain the required standards of safety. The need for legislation, in order to reduce the large numbers of accidents which were then taking place as a result of the use of X-rays, was discussed in Germany as long ago as 1905. Although no specific law resulted, nor is there any to-day in Germany covering the medical use of X-rays, the first rules for protection were drawn up and adopted in 1913 by the German Radiological Society. One of the earliest pieces of legislation was the New York City Ordinance of 1922, controlling the use of X-ray equipment. In the same year a law was introduced in Italy concerning the prospecting for, and use of, radioactive substances. Other countries introducing early legislation were Denmark, 1930, on the use of X-rays, Netherlands, 1931, X-rays and radioactive substances, and Finland, 1932, X-rays. It is not surprising that there was a great increase in regulations following the development and use of nuclear energy, and 16 of the 26 countries considered introduced legislation after 1945. In the United Kingdom, the first general law for the protection of both workers and public came into being with the passing of the Radioactive Substances Act of 1948, and in the U.S.S.R. the first general regulations appeared in 1953.

One example, concerning the employment of women on radioactive work, will suffice to demonstrate the importance of national characteristics, namely, that few countries would find it easy to follow Spain in enforcing a law which excludes from work with ionizing radiations all spinsters who are to be married within 3 months.

There is, however, general agreement between countries on the maximum permissible doses of radiation, and this is essentially the result of the fact that most legislation is based on the recommendations of the International Commission on Radiological Protection.

It is right that there should be international agreement about hazards which sometimes arise because of the gratuitous irradiation of people who have had no concern with the production of the source of the ionizing radiations, for example, from the testing of nuclear weapons, or, more peacefully, from the transport of radioactive sources. Furthermore, in view of the public's apprehension about the effects of radiation at the present time, it is, presumably, easier for most countries to fall in line, rather than disagree, with a body so authoritative and internationally constituted as the International Commission on Radiological Protection. Nevertheless, it will be surprising if, eventually, there are not some differences in the standards used in different countries, in any event for sources which are both generated and applied within their own frontiers. Already, the concept of maximum permissible dose is under review by the International Commission itself and there is a growing awareness of the statistical nature of the risks involved. According to present belief, there is no absolute safe limit on dose, only a diminishing risk as the dose decreases. It is not easy to see, therefore, how there can be international agreement about limits on dose which are equally acceptable to all countries. A degree of risk which is totally unacceptable in a well-developed country might seem trivial by comparison with the other risks of life, for example, from famine and disease, in a country the development of which may well depend on the use of nuclear energy. Mankind has always taken risks in order to improve his ultimate well-being, and no doubt, if the need arises, he will do so again in making use of ionizing radiations. Already, there have been some rejections of the standards set by the International Commission on Radiological Protection when their realization became either too inconvenient or too expensive. For example, some countries find it impracticable in certain industries to reach the present International Commission on Radiological Protection standard relating to the concentration of radon in air, a fact which is acknowledged by the International Atomic Energy Agency in its *Safety Series* No. 9, 1962. However, other countries, as exemplified in the World Health Organization's survey, have adopted the higher standards and presumably intend to reach them by

\* World Health Organization. *Protection Against Ionizing Radiations: Survey of Existing Legislation*. (Offprint from Vol. 15, No. 2 of the *International Digest of Health Legislation*.) Pp. 170. (Geneva: World Health Organization; London: H.M.S.O., 1964.) 6 Sw. francs; 10s.; 2 dollars.

increased expenditure and effort on improved ventilation and containment of the source of radon.

As this survey shows, there is wide divergence of views on the legislation which is necessary to ensure the safe use of ionizing radiations. It will be surprising if a future

edition of *Protection Against Ionizing Radiations* does not also reveal a greater diversity of opinions on the acceptable limits of dose which reflect more closely the needs of individual countries.

J. VENNART

## MULTIPLE HIT FREQUENCIES IN FULLY CORRELATED FIRE

By E. R. TERRY

Technical Operations Incorporated, Burlington, Massachusetts

IN evaluating the effectiveness of high-firing-rate guns as air defence and air-to-ground weapons we are often interested in hit frequencies other than the 'no hits', or miss, frequency. Assuming the aimpoint does not move during the firing interval, we can readily determine other hit frequencies by an extension of the 'salvo' or 'shotgun' formula. More precisely we will develop a model for determining the probability of exactly  $m$  hits with  $n$  rounds when the distribution of shots is circular normal and centred at a point  $h$  units from the target origin.

Assume that the pattern of weapons is released at a circular target of radius  $R$  with a bivariate circular normal aiming error characterized by a standard deviation  $\sigma_A$ . Each weapon in the pattern is distributed about the mean point of impact with a bivariate circular normal ballistic dispersion and is characterized by a standard deviation  $\sigma_B$ . The ballistic dispersion for each of the weapons comprising the pattern and the aiming error are mutually independent.

The probability that the  $i$ th round strikes the target of area  $A$  is:

$$p_i = \frac{1}{2\pi\sigma_B^2} \iint_A \exp\left[-\frac{1}{2\sigma_B^2}((x-h)^2 + y^2)\right] dx dy \quad (1)$$

Transforming to polar co-ordinates we obtain:

$$p_i = \frac{1}{2\pi\sigma_B^2} \int_{\theta=0}^{2\pi} \int_{r=0}^R \exp\left[-\frac{1}{2\sigma_B^2}(r^2 + h^2 - 2rh \cos \theta)\right] r dr d\theta \quad (2)$$

Rewriting equation (2) as follows:

$$p_i = \left(\frac{1}{\sigma_B^2} \exp\left[-\frac{h^2}{2\sigma_B^2}\right] \int_{r=0}^R r \exp\left[-\frac{r^2}{2\sigma_B^2}\right] \left(\frac{1}{2\pi} \int_{\theta=0}^{2\pi} \exp\left[\frac{rh \cos \theta}{\sigma_B^2}\right] d\theta\right) dr \right) \quad (3)$$

we see:

$$\frac{1}{2\pi} \int_{\theta=0}^{2\pi} \exp\left[\frac{rh \cos \theta}{\sigma_B^2}\right] d\theta = J_0\left[\frac{ih}{\sigma_B^2}\right] = I_0\left[\frac{rh}{\sigma_B^2}\right] \quad (4)$$

which is the zero-ordered Bessel function of pure imaginary argument. Accordingly equation (3) becomes:

$$p_i = \left(\frac{1}{\sigma_B^2} \exp\left[-\frac{h^2}{2\sigma_B^2}\right] \int_{r=0}^R r \exp\left[-\frac{r^2}{2\sigma_B^2}\right] \left(I_0\left[\frac{rh}{\sigma_B^2}\right]\right) dr \right) \quad (5)$$

Since the ballistic dispersions of all the rounds comprising the burst are independent of one another, the conditional probability that exactly  $m$  weapons will hit the target if a pattern of  $n$  weapons is released is  $\binom{n}{m} p_i^m (1-p_i)^{n-m}$  if we assume the resulting hit frequencies are binomially distributed. To obtain the unconditional probability that the centre of the distribution of shots is a distance  $h$  units from the target centre and that exactly  $m$  weapons will hit the target, we must multiply the expression above by the probability of the centre of this distribution of shots being so located.

The probability density function for determining whether the centre of the distribution of shots is within an annulus of width  $dh$  at a distance  $h$  units in any direction from the centre of the target is:

$$dp_h = \frac{1}{\sigma_A^2} \exp\left[-\frac{h^2}{2\sigma_A^2}\right] h dh \quad (6)$$

Multiplying equation (6) by the conditional probability that if the centre of the distribution of shots is so located exactly  $m$  rounds will hit the target, we get the corresponding probability density function:

$$\begin{aligned} dp_{[n,m]} &= dp_h \binom{n}{m} p_i^m (1-p_i)^{n-m} \\ &= \frac{1}{\sigma_A^2} \exp\left[-\frac{h^2}{2\sigma_A^2}\right] \binom{n}{m} p_i^m (1-p_i)^{n-m} h dh \quad (7) \end{aligned}$$

where the  $p_i$  are a function of the  $h_i$ . Integrating equation (7), we obtain for the unconditional probability that exactly  $m$  weapons will hit the target when a burst of  $n$  rounds is fired:

$$P_{[n,m]} = \frac{1}{\sigma_A^2} \int_0^\infty \exp\left[-\frac{h_i^2}{2\sigma_A^2}\right] \binom{n}{m} p_i^m (1-p_i)^{n-m} h_i dh_i \quad (8)$$

Equation (8) can be evaluated numerically by employing the Laguerre-Gauss quadrature formula.

The model outlined here has been programmed in *Fortran* for the IBM 7090/7094. Tables for facilitating a quick solution of equation (8) for any  $m$  and  $n$  are at present being compiled and will be submitted for publication in the near future.

## OPTICAL PROPERTIES OF URANIUM OXIDES

By DR. J. M. JONES and DR. D. G. MURCHISON

Department of Geology, University of Newcastle upon Tyne

WE were recently asked to investigate the optical properties of uranium oxides in the composition range  $\text{UO}_{2.00}$ - $\text{UO}_{2.25}$  as part of a research programme being carried out by the Reactor Group at the U.K.

Atomic Energy Authority Establishment, Dounreay, Scotland. It was hoped to establish: (1) that a satisfactory correlation existed between the optical properties of the oxides and their oxygen/metal ratios; (2) if this were the

case, that the method employed could give a sensitivity of  $\pm 0.01$  on the oxygen/metal ratios, particularly in the examination of sintered pellets and powders which are finding increasing use and application in technology and industry. The results obtained so far are encouraging and suggest that both aims stated above will be fulfilled.

Pellets have been prepared at Dounreay by sintering uranium oxide powder at  $1,450^\circ\text{C}$  in an atmosphere of carbon dioxide. A number of pellets in the composition range  $\text{UO}_{2.00}\text{--}\text{UO}_{2.21}$  have been provided. Sintered pellets are not, however, the most satisfactory materials for the collection of the initial optical data on which to establish reliable relationships with oxygen/metal (O/M) ratios. Attempts are therefore being made in this department to produce single crystals of uranium oxides with varying O/M ratios to act as reference materials. Up to now only crystals prepared in the manner described by R. G. Robins<sup>1</sup> have been examined optically. Briefly, this method involves electrolysis of uranyl chloride in a fused melt of potassium and sodium chlorides mixed in equimolar proportions. After chlorinating the melt to remove hydroxide impurities, and later to dissolve sufficient powdered uranium dioxide to yield an optimum concentration of 2.5 g  $\text{UO}_2/\text{Cl}_2/100\text{ g}$  solvent, the electrolysis is carried out for 20 h at  $830^\circ\text{C}$  using an applied potential of 100–250 mV and a cathode current density of 4 m.amp/cm<sup>2</sup>. So far as possible the optimum conditions recommended by Robins have been maintained; but certain changes in cell size and melt volume have been necessary. Despite the modifications, satisfactory crystals of cubo-octahedral habit of up to 0.5 mm in diameter have been obtained. Analysis by thermobalance of crystals from two sections of the platinum cathode gave O/M values of 2.002 and 2.003. X-ray analysis of crystals from the same areas of the cathode gave lattice parameters good for stoichiometric  $\text{UO}_2$ .

The optical parameter of the oxides measured is their specular reflectivity. This is obtained by comparing the intensity of light from the oxide with that from a standard of known reflectivity. In this case diamond has been used because of its low dispersion and the proximity of its reflectivity to those of the oxides. Reflectivities in air and oil of known refractive index have been measured, thus allowing calculation by Beer's equation of the refractive and absorptive indices of the oxides.

Because of the tendency of the uranium oxides to take on oxygen at a rate which is probably sufficient to cause a significant alteration of their surface properties over relatively short periods of time, the oxides are kept in an inert atmosphere. The reflectivity measurements and the last stages of polishing of the samples are therefore made in a glove box kept at a low positive pressure with nitrogen. A Leitz 'Epilux' microscope has been sealed just above the level of its vertical illuminator in the box and adjusted in the manner prescribed by M. Berek<sup>2</sup> for reflectivity measurements. After light from the specimen has left the microscope eyepiece, it passes into equipment similar to part of that designed by F. Gabler, W. Gubisch, W. Lipp and O. Rüker<sup>3</sup> for reflectivity determinations. This part consists essentially of a reflex housing, fitted immediately above the eyepiece, followed in the optical train by a plano-convex lens and then one of a series of apertures. These are contained on a silvered surface which makes it possible to observe with the reflex housing the size and position of the aperture in use in relation to the specimen in the field view of the microscope. The actual field sizes on which reflectivities can be measured vary from 4 to  $100\mu$ .

Before the light finally reaches the cathode of an 11-stage photomultiplier, it passes through one of a number of Schott interference filters. Output from the photomultiplier is fed into a pen recorder instead of more conventionally in reflectivity systems into a high-sensitivity galvanometer. This allows long series of measurements to be made without the operator having to remove his

hands from the box, thus preventing errors of measurement due to loss of focus on the microscope which occurs when the internal pressure of the box is altered by movement of the operator's hands.

Difficulties may arise when measurements are made on sintered samples because of the pores, flaws and defects resulting from the sintering process. To measure reflectivities on the surfaces of such samples, as small a field of view as possible has to be used. With a small aperture and a high-power air objective (N.A. 0.85, mag.  $\times 45$ ), the diameter of the field can be reduced to  $4\mu$ . Repeatability of measurements on sinters lies within  $\pm 1$  per cent of the reflectivity of the oxide, but on single crystals that yield polished surfaces of very high quality, greater accuracy is possible.

Reflectivities in air of three sinters with different O/M ratios, and one set of pure single crystals, have been measured at 4030, 4480, 5020, 5460, 5900, 6520 and 7090 Å. These results are plotted in Fig. 1. It appears that for the uranium oxides the maximum change of reflectivity with O/M ratio occurs towards the extremes of the visible spectrum with much less differentiation around 5000 Å. This observation corresponds in general with the results of R. J. Ackermann, R. J. Thorn and G. H. Winslow<sup>4</sup>, who plotted optical densities of uranium dioxide films against wave-lengths, and with the trends of diffuse reflectance with wave-length on bulk uranium dioxide reported by Companion and Winslow<sup>5</sup>.

It is unfortunate in the present experiments that the convenient high-intensity tungsten filament lamp used as a light source for the microscope has a low intensity in the blue and that the photomultiplier now in operation has a much reduced sensitivity around 7000 Å. These factors at present reduce the accuracy of measurement in the two most desirable regions of the visible spectrum. Measurements are now primarily being made at 4030 Å, where the spectral response of the photomultiplier is strong. The results so far suggest that, even with the tungsten lamp and its low efficiency at this wave-length, the desired differentiation between the different sintered oxides will be achieved. It does seem, however, that the reflectivity values measured on the sinters will be much more liable to influence of polishing technique than other materials such as coal constituents and many ore minerals.

Fig. 1. Reflectivities of uranium oxides with different oxygen/metal ratios plotted against wave-length. x,  $\text{UO}_{2.002}$ ; ●,  $\text{UO}_{2.104}$ ; +,  $\text{UO}_{2.151}$ ; ○,  $\text{UO}_{2.203}$ .

We thank the U.K. Atomic Energy Authority, Dounreay Reactor Establishment, for a grant. We also thank Mr. N. Parkinson and Mr. S. Pickles of the Reactor Group at Dounreay and Dr. T. Dickinson of the Chemistry Department, University of Newcastle upon Tyne, for their advice.

## MOLECULAR HYPOTHESIS OF FLAGELLAR ACTIVITY

By DR. N. R. SILVESTER and DR. M. E. J. HOLWILL

Department of Physics, Queen Elizabeth College, London, W.8

**ANALYSES** of the effect of temperature on flagellar movement involve a consideration of chemical kinetics and, following a recent investigation of this topic<sup>1</sup>, we have been tempted to speculate at a molecular level on the basis of flagellar contraction.

Several stroboscopic and high-speed cine-photographic investigations<sup>2-5</sup> have revealed that cilia generally execute an oar-like beat followed by a recovery stroke offering little resistance to movement, while many flagella maintain two- or three-dimensional waves along their length. Hydrodynamic equations derived by several authors<sup>6-13</sup> relate the propulsive velocity of a flagellated organism to the wave-length, amplitude and frequency of beat. Equations of a similar nature<sup>13,14</sup> enable one to evaluate the energy expended externally by an undulating flagellum, while the presence of a sustained amplitude along its length is held to show<sup>7,15</sup> that chemical energy is used over the whole extent of an organelle.

The fine structure of cilia and flagella has been well established by electron microscopy<sup>16-18</sup> although the functions of the several components are the subject of discussion. Within the flagellar membrane is the well-known 9 + 2 array of fibrils extending the length of an organelle. Each of the nine peripheral fibrils is in fact a doublet and possesses pairs of arms pointing towards an adjacent fibril. Between the central pair and the outer nine is a set of nine secondary fibrils or radial spokes joining the peripheral to the central fibrils.

The reactivation of glycerol-extracted cilia and flagella by ATP<sup>20-23</sup> has led to the suggestion that the dislocation of the terminal phosphate bond in ATP may be the source of energy for their movement. The way in which the chemical energy is released in a controlled manner is uncertain, but it is accepted that a motile flagellum must possess elements for contraction and compression and, further, a means for propagating waves along its length.

From the foregoing summary it is evident that there are many diverse approaches to the problem of flagellar motility, but in general the discussions in the literature have tended to be confined within the limits of a particular discipline. Now that more structural and chemical knowledge is becoming available and the interpretation of electron micrographs is concerned with structural sub-units of molecular dimensions, it will be useful to have some working hypothesis formulated in molecular terms which will provide a basis for general discussion. In the model that we propose below we have not attempted to satisfy or explain the multitude of observations in the literature, but have tried rather to devise a plausible system which will suggest further lines of thought.

**Résumé of relevant data.** The main items that should be incorporated in a flagellar model would seem to be: (i) A cyclic system of local contractions. (ii) The outer nine fibrils of the flagellum. (iii) The composition of the fibrils and probable existence of sub-units. (iv) The theory of mechanical propagation of contractile stimuli put forward by Machin<sup>15,24</sup>. (v) The ATPase activity of flagella and the dependence of their wave-form and frequency on ATP concentration. (vi) The relation

between the flagellar system and the actinomyosin system, especially in the light of a recent paper on the behaviour of F-actin<sup>25</sup>.

Because a sliding-filament mechanism operates in striated muscle it has been considered a possibility in the movement of flagella. Afzelius<sup>16</sup>, Gibbons and Grimstone<sup>18</sup> and Satir<sup>26</sup> discuss such a mechanism, but it is discarded by Gibbons and Grimstone on the grounds that to sustain a wave on a flagellum would require simultaneous extensions and contractions at different points on the same fibril. A more attractive system is one which assumes<sup>19,24</sup> active longitudinal contraction of regions of the flagellar structure. The nine peripheral fibrils are generally credited with the contractile function<sup>27</sup>, and we shall follow this assumption, in which each fibril is supposed to be made up of a series of contractile units<sup>15,7</sup>. The structure of these double fibrils, with their typical 'figure-of-eight' appearance in cross-section and their rows of projections or 'arms', has been described by several authors<sup>16,18,19</sup>, and more recently evidence of finer structure has been adduced. André and Thiéry<sup>28</sup> have observed the fibrils to be composed of 35-Å diameter protofibrils with a longitudinal periodicity of about 80 Å, and Pease<sup>29</sup> has found substantially the same arrangement.

A means by which local contractions may be propagated along a fibril has been suggested by Machin<sup>15</sup>. In this mechanical process a contractile unit is activated on deformation by a passively propagated wave from a neighbouring region of the flagellum. If the relation between tension and length of a contractile unit is non-linear, and there is a delay between the change in length and the development of tension, Machin<sup>24</sup> has shown that waves will arise spontaneously on a flagellum. In such a system the frequency of propagation can be controlled by altering the mechanical impedance at the proximal end of the flagellum. Holwill<sup>30</sup> considers that, although a mechanical system could be responsible for wave propagation, a control system is necessary for the initiation of a wave.

Chemical investigations of cilia<sup>27,31</sup> are not yet at the stage of characterizing the protein of the fibrils, but Gibbons<sup>27</sup> has reported the existence of a 25 S particle in solutions of ciliary protein. The particle has ATPase activity, is possibly associated with the 'arms', and is suggested by Gibbons to be a naturally occurring sub-unit of the cilium. The ATPase activity of flagella has also been demonstrated in the outer fibrils by Nelson<sup>32</sup> using cytochemical techniques, and the dephosphorylation of ATP is generally agreed<sup>21</sup> to be the source of energy for flagellar movement.

**Stimulation of the contractile unit.** The observations summarized here suggest that chemical energy supplied to the flagellum is used in the change of shape of contractile units composing the fibrous structure, and the theory of Machin<sup>15</sup> suggests how the contraction of individual units may be stimulated. In this theory the stimulus to contraction is conveyed mechanically, by the passive propagation of the flexional wave along the flagellum. The physical implications of this process appear to be satisfied

in practice<sup>30</sup> so that so far as we know this is a feasible system. We may imagine that the contractile unit in the fibril, before the peak of the contraction wave reaches it, is in some physico-chemical metastable state, and that the passive deformation conveyed by the wave momentarily alters the steric and electrostatic environment of the unit so that it is able to contract into an energetically more favourable conformation. The flagellum thus undergoes a kind of forced simple harmonic motion. The velocity of the passive wave along the flagellum is inherently dependent on the mechanical properties of the organelle and of its environment, but at the same time determines the rate of transmission of the forcing vibration. The stimulus to contraction could take effect in at least three ways, two of which we hope to eliminate at a later stage:

(a) The stimulus makes it possible for the contractile unit to interact with ATP molecules in its local environment, and use the dephosphorylation energy in changing its shape. (b) The unit is already 'primed' with ATP and the stimulus merely initiates the dephosphorylation and consequent contraction. (c) The stimulus raises the unit over a potential energy barrier so that it is able to contract to a state which is physically at a lower energy level; ATP is only used afterwards in the expansion of the unit to its previous metastable condition.

*Relation between chemical and structural sub-units.* A question which arises at this point is the relation between the contractile units we envisage and the observed fine structure of the outer fibrils. The experiments of Brokaw<sup>21</sup> with glycerinated models of *Polytoma* flagella may give a clue to the answer, for from his published measurements one can estimate (very approximately) the number of contractile units per flagellum. From his graphical presentation of the dephosphorylation of ATP by a suspension of flagella, we find the rate,  $V$ , of this process was in one instance 0.02 g of P per ml. per min. The concentration of flagella was  $1.5 \times 10^8$  in 20 ml. and that of the ATP was  $5 \times 10^{-5}$  M. At this concentration of ATP the rate  $V$  was almost independent of the substrate (ATP) concentration.

At high substrate concentrations the Michaelis-Menten law of enzyme kinetics (which is obeyed by the present reaction) reduces to the statement:

$$V = k[E]$$

where  $k$  is the limiting rate constant and  $[E]$  is the total concentration of enzyme<sup>33</sup>. If each contractile unit in the flagellum is activated  $f$  times per second, where  $f$  is the flagellar beat frequency, then  $f$  is also the limiting rate constant of the several chemical reactions which must occur in each contraction-relaxation cycle<sup>1</sup>. Let us define the size of the contractile unit to be that which is associated with one ATP molecule. If there are  $x$  units per flagellum and there are  $F$  flagella per litre, we can replace the molar concentration  $[E]$  by  $Fx/N_A$ , where  $N_A$  is Avogadro's Number. Thus we obtain:

$$V = \frac{fFx}{N_A}$$

Brokaw's values give  $V = 1.1 \times 10^{-8}$  M sec<sup>-1</sup> and  $F = 7.5 \times 10^9$  l.<sup>-1</sup>, so that  $fx = 9 \times 10^5$  units per flagellum per sec. The frequency of beat at an ATP concentration of  $5 \times 10^{-5}$  M is not given specifically by Brokaw, but is probably somewhere between 1 and 5 per sec. By making a guess at  $f = 3$  per sec, one finds a value for  $x$  of  $3 \times 10^5$  contractile units per flagellum.

On our hypothesis the contractile units are located in the outer fibrils so that  $3 \times 10^5$  units have to be fitted into 9 structures with an average length of about  $15\mu$  ( $15 \times 10^3$  Å). A short calculation shows that the effective length containing a contractile unit is equal to the number of units occurring in the cross-section of a fibril, multiplied by 4.5 Å. If, for example, one takes 18, the number of

35-Å 'protofibrils' suggested to be in the fibril by André and Thiéry<sup>28</sup>, one obtains an effective length of about 80 Å. The agreement of this length with the observed periodicity is coincidental, but these calculations do show that it is possible for the molecular units responsible for ATPase activity to be identical (in position or distribution) with the sub-units of which a fibril is composed.

*Role of ATP in the contraction phase.* The energy supplied by the measured rates of dephosphorylation of ATP has been noted by several authors<sup>21,34</sup> to be much in excess of the energy calculated to be necessary to propel the organism. The remainder of the energy is generally supposed to be dissipated in irreversible processes such as the non-elastic deformation of the flagellar structure, but another possibility is that there may be continuous ATPase activity in that part of the fibril which is under tension, in a way analogous to that suggested by Asakura, Taniguchi and Oosawa<sup>25</sup> for the isometric contraction of *F*-actin. However the energy is used, we know that something like  $10^5$ - $10^6$  contractile units per sec are activated in a flagellum, and that, if they are packed in the outer fibrils, they are probably separated longitudinally by a distance of the order of 100 Å. Since the wave velocity along flagella has been measured (about 250  $\mu$ /sec in *S. oncopelti*) (ref. 30) one can calculate the rate at which successive units are stimulated mechanically by the passage of the wave—for the values mentioned, the rate of progress of the stimulus along the fibril would be  $2.5 \times 10^4$  contractile units/sec. We can use this rate in order to decide whether type (a) of our proposed effects of stimulation is possible, that is, whether in fact it is possible for ATP to be exchanged in the contraction process within a reasonable time of stimulation.

The collision theory of reaction rates enables one to estimate the number of times per sec an ATP molecule in the local environment of the fibrils will make an effective collision with a sub-unit, and we can compare this rate with the rate of propagation of the stimulus. The number of effective collisions of unlike molecules  $A$  and  $B$  per c.c. per sec is given by the expression:

$$N_A N_B \sigma_{AB} \left\{ 8\pi RT \left( \frac{1}{M_A} + \frac{1}{M_B} \right) \right\}^{\frac{1}{2}} e^{-E/RT}$$

in which  $N$  is the concentration in molecules/c.c. and  $M$  the molecular weight of one reactant, and  $\sigma_{AB}$  is the mean diameter of the two molecules<sup>35</sup>. We put  $N_B = 1$  for the sub-unit (s.u.) in order to find the number of collisions/sec/s.u. and make the unit effectively stationary by letting  $M_B \rightarrow \infty$ . If we insert a physiological concentration of ATP ( $10^{-4}$  M) and a mean diameter of 30 Å, and use values for the molecular weight and activation energy of ATP of  $M_A = 500$ ,  $E = 10$  kcal/mole, we obtain a frequency of effective collisions of just less than 10 per sec at  $T = 300^\circ$  K. Since our calculated rate of stimulation is  $2.5 \times 10^4$  s.u. per sec it seems that collision processes are not able to supply ATP quickly enough for it to be exchanged in the contraction phase.

An alternative to exchange is that before the stimulus arrives, the ATP is already in position in the form of an ATP-sub-unit complex, the two components being presumably bound electrostatically in some way. Brokaw's finding<sup>21</sup>, that the dephosphorylation rate with glycerinated flagella became independent of ATP concentration above a certain level, is consistent with this idea, as this behaviour is characteristic of enzyme reactions in which an enzyme-substrate complex is formed<sup>33</sup>. The binding of ATP by molecules of a fibrous protein is not unlikely, as, for example, actin is known to form complexes with nucleoside phosphates and act as a dephosphorylating enzyme in certain circumstances<sup>25</sup>. The suggestion is that the ATP-sub-unit complex is the contractile unit of the flagellum, and that dephosphorylation occurs as a fairly fast process in the contraction phase. Since the total process is a cyclic one, this implies that the ADP

produced by contraction must be replaced by ATP in the relaxation phase, before the sub-unit is able to contract again.

*The relaxation phase.* On the foregoing hypothesis, it is in the relaxation phase and in the regeneration or replacement of ATP that the rate-limiting step occurs which must control the frequency of beat. In the living organism this step may be in some subsidiary metabolic process concerned with the re-phosphorylation of ADP (which could be still bound to the contractile unit, or free in 'solution' in the flagellum). It is to this limiting reaction that the values of activation enthalpy and entropy would apply which are derived, for example, from measurements of the thermal dependence of flagellar activity<sup>1</sup>.

In glycerinated models<sup>20,21,23</sup> the frequency of beat increases with increasing concentration of ATP in the medium, so that it seems in this case the ADP may be replaced directly by ATP by a diffusion-collision process. The rate of such a process would be directly dependent on the ATP concentration, and would control the rate of 'relaxation' of the contractile units and hence the frequency. It is interesting that the effective collision frequency which we calculated for an ATP concentration of  $10^{-4}$  M is about 10 per sec, while Brokaw<sup>21</sup> found that *P. uvella* models at this concentration had frequencies of beat "probably greater than 5 beats/sec". A collision process is thus able to supply ATP at rates of the right order of magnitude to sustain the flagellar motion.

The commonly noted phenomenon that excess ATP has a 'softening' or 'plasticizing' effect on flagella<sup>20,32,34</sup> may arise because the replacement of ADP by ATP on the sub-unit is necessarily concomitant with the release of tension. Nelson<sup>32</sup> states that flagella frequently appear rigid when ATP is washed out, which seems to agree with this hypothesis. We have suggested elsewhere<sup>1</sup> that the effect of ionic strength on the flagellar frequency may arise because the limiting reaction involves ions of like charge. If, as we propose, the limiting step is the replacement of ATP in the relaxation phase, the 'softening' effect of an increase in ionic strength<sup>20</sup> may be due merely to the speeding-up of the rate at which this replacement occurs.

The action of ATP as a 'relaxing factor' is also indicated by the effect of ATP concentration on the flagellar amplitude. If the bending of a flagellum is due to the contraction of a number of sub-units, each by a fixed amount, then the amplitude of bending will be related to the number of sub-units which are in the contracted state at a given time. The shorter the time after stimulation for which the contractile unit maintains tension, the smaller will be the number of units under tension at a given time (see Fig. 1). Since the tension 'decay time' will depend on the rate of interaction of sub-units with the relaxing factor one would expect the amplitude to decrease as the concentration of this factor increases. This, in fact, is the behaviour described by Brokaw<sup>21</sup>, who found that as

Fig. 1. Proposed events in the contraction-relaxation cycle of a hypothetical flagellar model.  $P$  is the probability that a given contractile unit will be in the contracted state. The phase,  $\phi$ , in the cycle can be interpreted either as a measure of time at a fixed point in the flagellum or as a measure of distance along the flagellum at a given instant.

the ATP concentration was raised towards  $10^{-3}$  M frequency increased but amplitude decreased—thus ATP is both regenerating the system (controlling frequency) and relaxing tension (controlling amplitude).

*The occasion of ATPase activity.* Although in the preceding discussion we have implicitly taken alternative (b) of the effect of stimulation (that is, that the contractile unit dephosphorylates bound ATP in the contraction phase) the merits of (c) have yet to be considered. In (c) the contraction is purely a physical process in which the unit contracts to a lower energy state, and in contrast to (b) the dephosphorylation occurs in the relaxation phase on restoring the unit to its expanded state. In both (b) and (c) the interaction with free ATP occurs on relaxation, so that most of the previous argument on the effect of ATP on frequency and amplitude applies to either alternative.

One way to distinguish between the two cases would be to find whether dephosphorylation accompanies the contraction or the expansion of the unit. Because the flagellar action is a cyclic one there is little hope of determining this unless the flagellar proteins can be isolated, when one might hope to follow conformational changes in the ATPase component by the methods of physical chemistry. Such an approach, if successful, could overcome another disadvantage of the cyclic system, namely, that observations on the motion of whole flagella can only yield activation energies. If the contractile protein itself were available there would be a possibility of determining equilibrium constants in the contraction process and hence of finding the free-energy change associated with dephosphorylation.

Another point which distinguishes (b) from (c) is that we conceive the contractile unit in (b) to be bound to a nucleoside phosphate molecule for most of the period of the contraction-relaxation cycle, whereas this is not a necessity for the case in which the contraction is purely a physical process. One can only judge between the two systems on the basis of probabilities, but we have an interesting comparison in the behaviour of *F*-actin under sonic vibration. Asakura, Taniguchi and Oosawa<sup>25</sup> found that the *F*-actin could split ATP when in a sonic field, although normally this protein is associated with bound, non-reactive ADP<sup>27</sup>. They explain the details of this behaviour briefly as follows. The partial disruption of the fibrous structure which is produced by mechanical means allows bound ADP to be replaced by ATP from the medium, which is then split as ruptured intermolecular bonds are re-formed. The chemical energy provided by the ATP-splitting accelerates the restoration of the filament to its uninterrupted state. Continuous sonic bombardment thus results in a cyclic process in which regions of the filament are continually being interrupted and re-formed, with the consequent splitting of ATP. The parallels are obvious between this system and the proposed mechanical stimulation of flagellar contraction, and favour that alternative in which the contractile unit remains bound to nucleoside phosphate and splits ATP in the contraction phase. (If the outer fibrils of the flagellum do, indeed, behave in this actin-like way, it would explain many of the muscular properties which are exhibited by flagella.)

*The proposed model.* It remains now to summarize the hypothetical system at which we have arrived in this discussion. To begin with the structure, we suppose that the outer nine fibrils of the flagellum are capable of longitudinal contraction at localized regions. The contractile capacity is a property of units in the fibril which are identical in distribution (and probably *in toto*) with the structural sub-units of which a fibril is composed. The contractile units are associated with a bound adenosine phosphate molecule for most of the period of the flagellar beat.

The contraction cycle begins (Fig. 2) when a mechanical deformation, conveyed passively along the beating flagel-

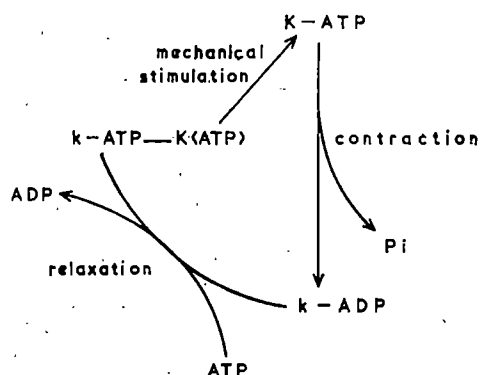

Fig. 2. Proposed chemical changes in the contraction-relaxation cycle of a hypothetical flagellar model. *K* denotes the 'normal', and *k* the contracted, state of a fibrillar sub-unit. The ATP shown in parenthesis is presumed to be masked and inactive. The processes, *k*→*K* and the exchange of ATP, could be simultaneous or in the reverse order.

lum, stimulates a particular sub-unit to split the ATP with which it is bound. Energy from the dephosphorylation enables the unit to change its conformation and, in so doing, perform external work on the flagellar system. The contraction follows quickly after stimulation, so that the contraction phase probably lasts for less than a tenth of the flagellar period. After contraction, the unit maintains tension until 'relaxed' by some factor which may be ATP itself. The bound ADP which remains after dephosphorylation is then exchanged with free ATP in the local environment. The rate of the relaxation process governs the amplitude of beat. When the unit again has a bound ATP molecule, it is ready to take part anew in the contraction cycle. The rate of replacement of ATP controls the frequency of beat.

In considering this model we have only discussed the possible role of the outer fibrils, from a rather mechanical point of view. The functions of the rest of the intricate flagellar structure, and the chemical aspects of ATPase activity and relaxation, promise levels of complexity which at present are beyond speculation. The few quantitative results on which we could draw, even for the

present discussion, show how much remains to be done in this field; however, the model may serve as a framework for further experiment, to be discarded when a better hypothesis can be devised.

We thank Prof. R. E. Burge and Mr. M. R. Watson for helpful discussions.

## INCREASED SENSITIVITY OF MICROSOMES FROM PHENOBARBITAL-TREATED RATS TO SYNTHETIC MESSENGER RNA (POLYURIDYLIC ACID): LACK OF EFFECT ON RIBOSOMES

By R. KATO\*, L. LOEB† and Dr. H. V. GELBOIN

Carcinogenesis Studies Branch, National Cancer Institute, and Laboratory of Chemical Pharmacology, National Heart Institute, Bethesda, Maryland

THE *in vivo* administration of phenobarbital increases the activity of several rat liver microsomal enzyme systems<sup>1</sup>. Present evidence suggests that the phenobarbital-induced increases in enzyme activity are due to enzyme synthesis. Thus, the stimulatory effect of phenobarbital on one of these enzymes, amino-azo dye demethylase, is prevented by the simultaneous administration of puromycin<sup>2</sup>, an inhibitor of protein synthesis at the microsomal level. Further, microsomes isolated from phenobarbital-treated rats have a greater activity both *in vivo*<sup>3</sup> and *in vitro*<sup>4</sup> in the incorporation of DL-leucine-<sup>14</sup>C into protein than do microsomes isolated from control animals. As a part of an investigation on the mechanism of the increased incorporation, we examined the effect of

phenobarbital pretreatment on the ability of isolated microsomes and ribosomes to incorporate phenylalanine into protein and the sensitivity of these preparations to the addition of synthetic messenger RNA, that is, polyuridylic acid.

Groups of four Sprague-Dawley female rats, weighing 160–170 g, were injected intraperitoneally with 80 mg/kg of sodium phenobarbital in 0.9 per cent sodium chloride at 42 and 18 h before decapitation. Controls were given saline only. After the 40-h period, the livers were removed, homogenized in 5 volumes of 0.25 M sucrose, and the pooled homogenates were centrifuged for 10 min at 12,000g to sediment the nuclear and mitochondrial fractions. The microsomal fraction was separated by centrifugation at 100,000g for 2 h and then re-suspended in 10<sup>-3</sup> M tris-HCl pH 7.5, 1.5 × 10<sup>-3</sup> M MgCl<sub>2</sub> and 5 × 10<sup>-3</sup> M KCl at a protein concentration of 17.5 mg/ml.

\* Present address: Laboratory of Pharmacology, National Institute of Hygienic Science, Tamagawa, Joga, Setagayaku, Tokyo, Japan.

† Present address: University of California, Berkeley, California.

Liver ribosomes were isolated by treating an aliquot of the 12,500g supernatant with sodium deoxycholate according to the method of Korner<sup>5</sup>.

Livers from phenobarbital-treated rats weighed about 20 per cent more than livers from control animals; moreover, microsomal protein recovered per g of wet liver was increased about 24 per cent and microsomal RNA was increased generally by less than 10 per cent. Thus, the RNA/protein ratio was slightly decreased in phenobarbital microsomes. However, the ribosomal protein and RNA recovered/g of liver was about 25 per cent and 10 per cent respectively less in phenobarbital-treated animals.

Table 1. PHENYLALANINE INCORPORATION BY LIVER MICROSOMES AND RIBOSOMES FROM CONTROL AND PHENOBARBITAL-TREATED RATS

Contents	Pre-incubation	Additions	Phenylalanine-(U)- <sup>14</sup> C incorporation (c.p.m./mg protein)		
			Control	Pheno-barbital	Diff. (%)
Microsomes	None	None	87	186	+114
Microsomes	None	Polyuridylic acid (300 µg)	205	333	+62
Microsomes	Pre-incubated	None	3	5	—
Microsomes	Pre-incubated	Polyuridylic acid (300 µg)	215	430	+100
Ribosomes I	None	None	150	205	+37
Ribosomes I	None	Polyuridylic acid (300 µg)	274	283	+3
Ribosomes I	Pre-incubated	None	6	7	—
Ribosomes I	Pre-incubated	Polyuridylic acid (300 µg)	337	367	+11
Ribosomes II	None	None	170	200	+14

The reaction mixture contained in a final volume of 1.7 ml. the following: 20 µmoles potassium phosphate buffer pH 7.4, 2.5 µmoles ATP, 0.5 µmoles GTP, 87.5 µmoles sucrose, 100 µmoles reduced glutathione, 10 µmoles MgCl<sub>2</sub>, 40 µmoles phosphocreatine, 250 µg creatine phosphokinase, 0.2 ml. of 100,000g supernatant from control preparations containing 2.0 mg of protein and 0.4 ml. of the microsomal preparation (7.0 mg of protein) or 0.4 ml. of the ribosomal preparation (ribosomes I, 3.5 mg protein, ribosomes II, 3.0 mg RNA) and 0.085 µmoles of L-phenylalanine-(U)-<sup>14</sup>C (spec. act. 9.13 mc./mmole). Incubation was at 37° C for 15 min. The reaction was stopped with 1.7 ml. of 10 per cent trichloroacetic acid containing 0.1 per cent non-radioactive L-phenylalanine. The proteins were washed and counted as previously described<sup>6</sup>. The results given are the average of duplicate determinations. Pre-incubation\* was at 37° C for 12 min in the presence of all the co-factors but in absence of radioactive phenylalanine. After pre-incubation, the flasks were placed in ice and additional creatine phosphate (40 µmoles) of creatine phosphokinase (250 µg) and phenylalanine <sup>14</sup>C were added. Polyuridylic acid was added where indicated and the flasks were incubated as previously described.

Table 1 shows that microsomes isolated from phenobarbital-treated rats have 114 per cent greater L-phenylalanine-(U)-<sup>14</sup>C incorporating activity than do microsomes from control animals. In the presence of 300 µg of polyuridylic acid, the phenobarbital microsomes incorporate 62 per cent more L-phenylalanine-(U)-<sup>14</sup>C. Table 1 also shows the effect of phenobarbital pretreatment on the amino-acid incorporating activity of rat liver ribosomes. In contrast to the large differences observed in the microsomes, phenobarbital treatment caused only a 37 per cent increase in the incorporating activity of ribosomes. In the presence of 300 µg polyuridylic acid there was essentially no difference in the phenylalanine incorporating activity of control and phenobarbital ribosomes.

The addition of polyuridylic acid to different preparations of microsomes or ribosomes stimulates phenylalanine incorporation in varying amounts. Under the usual conditions in which polyuridylic acid is added to non-pre-incubated preparations, it is difficult to determine the sensitivity of the preparation to the added messenger RNA since one cannot differentiate between the amount of incorporation directed by the endogenous RNA compared with that directed by added messenger RNA (poly-U). In order to determine the sensitivity of the microsomes or ribosomes to added messenger RNA (poly-U), we removed endogenous RNA by a pre-incubation procedure<sup>6</sup> which makes phenylalanine incorporation totally dependent on added poly-U.

The phenobarbital microsomes are considerably more sensitive to added poly-U than are normal microsomes. Thus, after pre-incubation (Table 1) the addition of 300 µg of polyuridylic acid caused a 100 per cent greater phenylalanine incorporation in the phenobarbital micro-

Fig. 1. Effect of polyuridylic acid on phenylalanine incorporation

somes than in the normal control microsomes. Fig. 1 shows the effect of varying amounts of polyuridylic acid on phenylalanine incorporation in pre-incubated phenobarbital and control microsomes. Over a greater than four-fold range of added polyuridylic acid there is greater phenylalanine incorporation in the phenobarbital microsomes. At saturating levels of polyuridylic acid, the phenobarbital microsomes are 90 per cent more active than are control microsomes. This indicates that one of the effects of phenobarbital is to increase the sensitivity of the microsomes to the addition of messenger RNA. Our results are not due to a possible phenobarbital-induced decrease in microsomal nuclease activity and hence a decreased destruction of added messenger RNA, since the addition of more than twice the saturating level of polyuridylic acid does not increase incorporation in either preparation. One possible mechanism for the increased sensitivity of phenobarbital microsomes would be an increase in the number of microsomal sites capable of binding to messenger RNA.

Although phenobarbital microsomes are more sensitive to added poly-U, the sensitivity of ribosomes from both control and phenobarbital-treated rats was essentially the same. Poly-U addition stimulated phenylalanine incorporation in normal and phenobarbital pre-incubated ribosomes to the same extent. Thus, the increased sensitivity of phenobarbital microsomes seems related to factors which are removed by deoxycholate treatment. The major known component solubilized by deoxycholate treatment is the endoplasmic reticulum. It thus appears that phenobarbital alters the endoplasmic reticulum in a way that enables the ribosome-membrane complex (microsomes) to have a greater sensitivity for messenger RNA.

Our results are consistent with the suggestion<sup>8</sup> that the endoplasmic reticulum is an important component of mammalian protein synthesizing systems. Remmer and Merker have shown by electron microscopy that phenobarbital increases the amount of smooth membranes of the hepatic endoplasmic reticulum<sup>7</sup>. The results reported here are consistent with these findings and suggest the possibility that newly synthesized membrane components have increased activity in supporting amino-acid incorporation.

We thank Mrs. T. Ben for her help and Dr. J. R. Gillette for his encouragement.

# RIBOSOMAL AGGREGATES IN GAMMA-GLOBULIN SYNTHESIS IN THE RAT

By DR. GEORG MANNER and PROF. BERNARD S. GOULD

Department of Biology, Massachusetts Institute of Technology, Cambridge, Mass.

IT has been established in a number of instances that proteins are synthesized on polyribosomes (clusters of ribosomes held together by messenger-RNA). This mechanism was demonstrated to apply, among others, to the synthesis of haemoglobin,  $\beta$ -galactosidase and collagen<sup>1-3</sup>. While some of these proteins are made on polysomes of a size which is fairly uniform and roughly proportional to the size of the protein formed, collagen appears to be assembled on large polysomes of heterogeneous size distribution. Stenzel *et al.*<sup>4</sup> found that antibody synthesis in the rabbit spleen occurs on single ribosomes and concluded that antibodies may be composed of short protein or polypeptide sub-units much smaller than the light and heavy chains of 20,000 and 60,000 molecular weight units, respectively, that have been reported to constitute the gamma-globulin molecule, and that these short sub-units would then, by combination in different patterns, form antibodies of different specificities. Other recent work indicates, however, that rat liver proteins of average size can be formed on single ribosomes<sup>5</sup>.

We have investigated gamma-globulin synthesis in rat lymph nodes stimulated by *Salmonella* antigens and have found evidence indicating that, in this immune system, protein synthesis appears to take place both on single ribosomes and on ribosomal aggregates exhibiting unusual susceptibility to proteolytic enzymes and resistance to ribonuclease.

Rats were injected in the footpad with 0.1–0.4 ml. of suspensions of *Salmonella* antigens (obtained from Difco, Inc.). Some of the animals were killed during the primary responses after five days, others were given a second antigenic stimulus after a few weeks and killed four days later. The popliteal lymph nodes were excised and incubated for 10 to 30 min in Eagle's medium MEM (ref. 6) in which <sup>14</sup>C-labelled algal protein hydrolysates replaced the usual amino-acids. After the incubation the tissue was chilled, homogenized and subjected to density gradient centrifugation as previously described for a different system<sup>3</sup>. Fractions of approximately 1 ml. were collected and the absorbancy at 260 m $\mu$  and the trichloroacetic acid-precipitable radioactivity, indicating respectively the amount of ribosomal material and the protein-synthesizing activity, were determined in the individual fractions.

In Fig. 1 the distribution over the gradient of absorbancy and radioactivity of the ribosomal material derived from non-immunized rats is compared with that of material from immunized rats. In the homogenate from non-immunized lymph nodes the absorbancy at 260 m $\mu$  shows a maximum in the region of the single ribosomes. A small amount of polysomal material is broadly distributed over the gradient. There is very little amino-acid-incorporating activity, mainly located in the single ribosome region. In lymph node homogenates from immunized animals, on the other hand, a second, broader peak of absorbancy at 260 m $\mu$  and of radioactivity was consistently found in the heavier regions of the density gradient. No difference was noted between the distribution patterns of lymph node material derived from rats during the primary and the secondary response.

Paper electrophoresis of the medium after incubation indicated that radioactive gamma-globulin was being formed by the immunized tissue but not by the non-immunized tissue.

In many protein-synthesizing systems not treated with detergents such as sodium deoxycholate before gradient

centrifugation, a pellet of lipid-containing material forms on centrifugation. This pellet is presumably derived from the endoplasmic reticulum to which the ribosomal material is believed to be bound in such systems. Deoxycholate

Fig. 1. Distribution over a sucrose density gradient of ribosomal material and of amino-acid-incorporating activity in unimmunized (A) and immunized (B) rat popliteal lymph nodes. Lymph nodes were incubated in Eagle's medium MEM supplemented with <sup>14</sup>C-amino-acids for 20 min, cooled to 0° and homogenized. The homogenate was freed of heavy cell components by low-speed centrifugation, layered over a sucrose density gradient 15–30 per cent w/w containing 0.01 M KCl, 0.0015 M MgCl<sub>2</sub> and 0.01 M *tris* HCl, pH 7.4, and centrifuged for 120 min at 25,000 r.p.m. in *STV* 25 rotor of Spinco ultracentrifuge. S.R., single ribosomes

dissolves the membrane material and liberates the ribosomes or polysomes linked to it. In the lymph node system used by us no pellet was formed and deoxycholate was without effect on the distribution of the ribosomal material. This is surprising since plasma cells, which are generally accepted as the major source of immune proteins, are presumably rich in endoplasmic reticulum. The present observations suggest the possibility that in this system antibody formation occurs on ribosomes very loosely associated with the endoplasmic reticulum, or perhaps that some early transitory cell relatively poor in endoplasmic reticulum may in fact be involved in gamma-globulin formation.

Electron-microscopic examination of the material in the heavier peak showed a heterogeneous population of ribosomal aggregates ranging from closely-spaced dimers and trimers to less closely-spaced aggregates of up to six ribosomes. The wider spacing of these larger aggregates presumably accounts for the fact that they sediment more slowly than the closely-spaced polysomes found, for example, in the reticulocyte system<sup>1</sup>.

Characteristically, polysomes have been found to be disaggregated by mild ribonuclease treatment to form single ribosomes. This has been taken as supporting evidence for messenger-RNA being the agent which links the ribosomes together into polysomes. Unexpectedly, the ribosomal aggregates from immunized rat lymph nodes were found to be uncommonly resistant to ribonuclease action even at concentrations considerably higher (up to 10 times) than those sufficient to disaggregate polysomes in other systems. Fig. 2 shows that after ribonuclease treatment of lymph node homogenates from immunized rats the characteristic 'immune' peak of absorbancy and radioactivity is still present, while the small amounts of polysomes in the other regions of the gradient have been disaggregated in the usual manner. This resistivity to ribonuclease attack was also found when Taka-ribonuclease was used instead of pancreatic ribonuclease. Deoxyribonuclease was also without effect on the systems.

Fig. 2. Effect of ribonuclease on ribosomal aggregates from immunized rat lymph node homogenates. Conditions of incubation and centrifugation as in Fig. 1. *A*, No ribonuclease treatment. *B*, Homogenate treated with 6  $\mu$ g/ml. pancreatic ribonuclease at 0° for 10 min before gradient centrifugation

Fig. 3. Effect of trypsin and chymotrypsin on ribosomal aggregates from immunized rat lymph node homogenates. Conditions of incubation and centrifugation as in Fig. 1. *A*, Homogenate treated with 50  $\mu$ g/ml. trypsin at 20° for 5 min before gradient centrifugation. *B*, Homogenate treated with 50  $\mu$ g/ml. chymotrypsin at 20° for 5 min before gradient centrifugation

E. Bell has found (personal communication) that under mild conditions proteolytic enzymes can disaggregate polysomes to ribosomes rather than to ribosomal sub-units. In our investigation, preliminary experiments showed that mild trypsin treatment of chick embryo homogenates results in limited disaggregation of heavy polysomes and a corresponding increase in the amount of smaller and lighter polysomes. On the other hand, trypsin treatment of 'immune' lymph nodes under identical conditions results in almost complete disaggregation of the ribosomal aggregates and a corresponding increase in the single ribosomes (Fig. 3). Most of the radioactivity is lost from the particulate fraction by this treatment as the trypsin degrades the nascent polypeptide chains attached to ribosomal material into slowly sedimenting fragments. Identical results were obtained when mild chymotrypsin rather than trypsin treatment was applied. Control experiments with mixtures of chick embryo and lymph node homogenates revealed extremely low levels of endogenous nucleases in the lymph node homogenates and thus ruled out the possibility that the proteolytic enzymes remove a protective protein from the messenger-RNA and so allow subsequent attack by endogenous ribonucleases. Rather, it is concluded that the substance linking together the individual ribosomes of the 'immune' aggregates is indeed a polypeptide or protein. It is not clear whether such a protein serves specifically to link the ribosomes or whether the linkage is, in fact, through interaction of the nascent gamma-globulin chains.

This investigation was supported by a grant from the U.S. Public Health Service, National Institutes of Health.

# NEOPLASMS IN THYMECTOMIZED MICE FOLLOWING ROOM INFECTION WITH POLYOMA VIRUS

By DR. LLOYD W. LAW

National Cancer Institute, Bethesda, Md.

SOME strains of mice, particularly *C57BL*, are highly resistant to the oncogenic effects of polyoma virus even when virus is injected in the immediately postnatal period<sup>1,2</sup>. Highly susceptible mice of the strains that have been examined also usually do not develop neoplasms if they are 2 weeks old or older at the time of virus injection<sup>1</sup>.

In the case of *C57BL* mice, salivary gland rudiments in organ culture show the same proliferative response and transformation to the neoplastic state<sup>3</sup> as the gland rudiments of susceptible *C3H* mice to polyoma virus infection<sup>4</sup>. The process of control of the neoplastic conversion, therefore, appears to rest within the intact animal.

The obvious explanation for the susceptibility of most neonatal mice to polyoma virus is the inadequacy of the immune response and the readiness with which tolerance to foreign antigens can be established at this time. *C57BL* mice become immunologically competent soon after birth and are indeed relatively resistant to the induction of tolerance<sup>5,6</sup>. This explanation becomes more plausible when it is recognized that neoplasms induced with polyoma virus possess virus-specific new cellular antigens<sup>7,8</sup>. Both Habel<sup>7</sup> and Sjogren *et al.*<sup>8</sup> have interpreted their findings of resistance to challenge with isogenic transplantable polyoma tumours using the concept that polyoma virus transforms normal cells to neoplastic cells in the new-born and adult; the transformed cells containing the new cellular antigen provoke an immune response in adult but not in new-born mice. Neoplastic cells therefore arise after virus infection in the early postnatal period; they are tolerated and grow progressively. Adult animals are capable of rejecting in a homograft type reaction these tumour cells containing 'foreign' antigen.

That the low susceptibility of *C57BL* mice to polyoma virus oncogenesis has, in all probability, an immunological basis was shown in investigations using the early thymectomized animal<sup>9,10</sup>. Thymectomy during the immediately postnatal period is known to impair the maturation of immunological faculty<sup>11</sup>. More recently, it was shown that *C57BL* mice thymectomized at birth, and reconstituted with adult syngeneic spleen cells had their capacity to resist polyoma virus oncogenesis restored<sup>2</sup>.

The investigation recorded here was initiated to examine the effect of early thymectomy on the development of spontaneous mammary cancer in the females of a high mammary tumour strain and at the same time to investigate the effect of thymic removal on methylcholanthrene-induced fibrosarcomas in their male litter-mates.

*C3H/HeN* strain mice from the NIH colony were used. These were thymectomized at 3 days of age. Completeness of thymectomy was checked by serial sections of tissue obtained at necropsy from the upper mediastinal area. At least two members of each litter were left as intact controls. Litters were raised by their own mothers and at 4-5 weeks were separated according to sex, but with thymectomized and intact mice remaining together, 6-8 mice per cage. These mice were housed in an animal room containing other experimental mice, some of which had received polyoma virus parenterally. Females received no further treatment; males received 0.1 mg of 3-methylcholanthrene (MCA) dissolved in 0.2 ml. tri-

caprylin, subcutaneously, at 8 weeks of age. The mice were examined daily for neoplastic growths. Unexpectedly an untreated female developed bilateral parotid gland tumours when 4½ months old. At this time polyoma HI antibodies<sup>12</sup> were determined in the sera of both males and females. The members of 6 out of 15 litters of the untreated females showed HI antibodies ranging from 1:400-1:12,800. An HI antibody survey taken when the mice were 2 months of age showed all to have titres of < 1:100 (HI negative). Later, 9 additional females presented polyoma-type neoplasms but only those among the 23 thymectomized mice comprising the 6 HI-positive litters. All intact mice, showing nevertheless polyoma virus infection, remained tumour-free, as did all members of the 9 HI-negative litters (see Table 1).

Table 1. POLYOMA-TYPE NEOPLASMS IN *C3H/HeN* FEMALE MICE: 3-DAY THYMECTOMY AND ROOM INFECTION

Group	Polyoma HI antibodies (according to litter)			No. neoplastic No. mice	Latent period (months)
	+	-	Titre		
Thymect.	6	—	1:4,500*	10/23 (44%)	5.8 (4.5-6.5)
Intact	6	—	< 1:100	0/84	—
		9	1:600	0/15	—
		9	< 1:100	0/18	—

\* Seven mice that either had parotid gland tumours, or later became tumorous, had HI antibody titres of 1:6,400 or higher; otherwise the mean titres of polyoma-infected mice were nearly identical in thymectomized and intact mice.

The neoplasms, grossly, were confined to one or both parotid glands. Histological examination, however, also revealed numerous neoplastic areas in other salivary glands. The histological appearance of these neoplasms was similar to that described earlier<sup>13</sup>. There were poorly-defined tubular structures with a tendency toward loss of epithelial character and gain of spindle-cell features.

No differences were observed in the frequency or latent period of MCA-induced fibrosarcomas between 3-day thymectomized males and their intact litter-mates. Eighty-one per cent (47/58) of thymectomized mice, and 79 per cent of the controls (23/29), had neoplasms; the average latent periods (after carcinogen introduction) were 76 and 74 days, respectively. Among the 3-day thymectomized *C3H/HeN* males, only 23 were at risk to polyoma virus infection from 4½ to 6½ months, during the period when parotid gland tumours appeared in their female litter-mates; yet only one male mouse developed parotid gland neoplasms, and this was at 6 months of age although more than half had evidence of polyoma infection.

Mammary tumours are now appearing in the remaining *C3H* females, beyond 7½ months of age, and these have the typical morphology of such neoplasms arising in mice with the Bittner milk agent, reproducing mammary acini in many areas and for the most part classified as adenocarcinomas. The frequency of these neoplasms, however, is so far nearly the same in thymectomized and intact females (see ref. 14).

The pattern of spontaneous polyoma virus infection in animal colonies housing experimentally inoculated mice is in harmony with the observations reported earlier; *C3H* mice in our colony showed no polyoma HI antibodies at 2 months of age. At from 3 to 8 months approximately 30 per cent were infected and the infection rate increased to approximately 70 per cent at 12 months<sup>15</sup>, yet polyoma-type tumours were not observed in our *C3H* colony. Probably the only way in which the mouse, naturally

infected as an adult, can develop a polyoma-induced neoplasm is by the chance occurrence of an event which reduces its immunological competence. Thymectomy at 3 days appears to be more effective than X-irradiation in this respect. C3H mice, in the same colony, which received 300 r. or 150 r.  $\times$  4 whole-body X-irradiation, and of which 80 per cent had high levels of polyoma HI antibodies, failed to develop polyoma-type neoplasms.

The present findings are in accord with the concept that the basis of resistance to polyoma virus oncogenesis is a cellular immunity of the homograft type directed against virus-specific new antigen contained in the neoplastic cells. In the immunologically disturbed animal these antigens are not capable of provoking an immunological attack on the cells transformed to neoplasia by polyoma virus. These clones of cells therefore grow progressively into frank neoplasms.

The new cellular antigen must indeed be qualitatively similar to a minor histocompatibility antigen since the 3-day thymectomized C3H mice in this investigation showed normal bodily growth, were not deficient in lymphocytes (peripheral blood or lymphoid organs), were

capable of forming haemolysins in normal fashion to sheep red blood cells and rejected allogeneic skin grafts (AKR) at the same time as intact litter-mates.

## EFFECTS OF ADRENERGIC NEURONE-BLOCKING AGENTS ON THE SUBMAXILLARY GLAND OF THE CAT

By M. J. DAVEY, R. F. DAVIES, DR. H. REINERT and P. C. SCHOLFIELD

Department of Pharmacology, Pfizer Ltd., Sandwich, Kent

EMMELIN and Engström<sup>1</sup> reported that bretylium caused salivation in the submaxillary gland of the cat as a result of its muscarinic properties. They found that bretylium was without effect on the secretion of saliva and the vasodilatation evoked by electrical stimulation of the chorda tympani nerve. In contrast to the results of Emmelin and Engström, we have found that in addition to abolishing the vasoconstrictor and secretory effects of sympathetic stimulation, and possessing muscarine-like activity in this organ, bretylium reduces the secretory and vasodilator effects of chorda stimulation. This was found to be a general property of adrenergic neurone blocking agents. Fig. 1 shows that guanoxan, guanethidine, and bretylium antagonize not only the vascular and secretory effects of sympathetic stimulation but also those of parasympathetic stimulation.

According to Hilton and Lewis<sup>2-4</sup>, there is no vasodilator innervation in the cat submaxillary gland; and both the atropine-resistant vasodilatation evoked by chorda stimulation and the after-vasodilatation which follows sympathetic stimulation are caused by a plasma kinin which is indistinguishable from bradykinin. These conclusions have been challenged by Schachter and his colleagues<sup>5,6</sup>, who consider that the chorda tympani nerve contains vasodilator fibres; this view is consistent with that originally held by Dale and Gaddum<sup>7</sup>. The antagonism of the vasodilator effects of chorda stimulation by adrenergic neurone-blocking agents suggested to us the possibility that an adrenergic mechanism may be involved in the vasodilatation. For example, acetylcholine released from the nerve endings of the chorda tympani may excite the nerve endings of sympathetic postganglionic adrenergic C fibres and release noradrenaline/adrenaline in close proximity to vascular  $\beta$ -receptors; or the chorda tympani nerve may innervate chromaffin tissue within the submaxillary gland.

It could be argued that the antagonistic effects of adrenergic neurone-blocking agents on the atropine-resistant hyperaemia evoked by chorda stimulation resulted from a general change in the state of the systemic circulation. However, it can be seen, in Fig. 2, that close arterial injections of small amounts of guanethidine directly into the blood supply to the submaxillary gland abolished the vasodilatation evoked by chorda stimulation at a time when vasoconstriction still accompanied sympathetic stimulation. The secretory effects of sympathetic stimulation and the after-vasodilatation which follows sympathetic stimulation were abolished by even smaller amounts of guanethidine injected close-arterially; these amounts did not affect the secretory and vasomotor effects of chorda stimulation (Fig. 2).

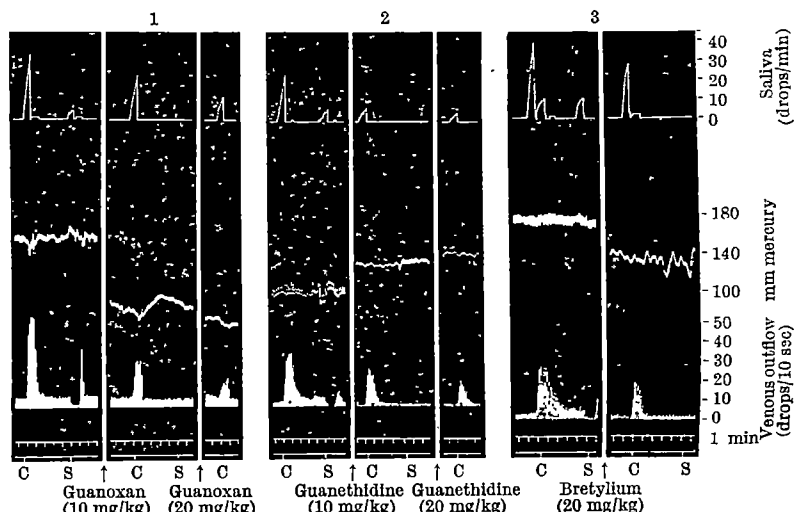

Fig. 1. Effects of intravenous injections of guanoxan (1), guanethidine (2) and bretylium (3) on the cat's submaxillary gland. Chloralose anaesthesia. Top tracing: secretion of saliva. Middle tracing: mean arterial pressure. Bottom tracing: venous outflow. Stimulation of the chorda tympani (C) and cervical sympathetic (S) with supramaximal pulses (20 V; 0.5 msec; 10/sec; 60 sec). Note: guanoxan, guanethidine and bretylium in addition to antagonizing the effects of sympathetic stimulation also antagonized the effects of parasympathetic stimulation.

Fig. 2. Cat, 2.5 kg, ♀. Chloralose anaesthesia. Record of salivary secretion from the submaxillary gland (top), mean arterial pressure (middle) and venous outflow (bottom). Stimulation of the chorda tympani (C) and the cervical sympathetic (S) with supramaximal pulses (20 V; 0.5 msec; 10/sec; 60 sec). Guanethidine and atropine given by close-arterial injection. Note: guanethidine abolished the after-vasodilatation which followed sympathetic stimulation and the atropine-resistant hyperaemia evoked by chorda stimulation

Fig. 3. Cat, 3.0 kg, ♂. Chloralose anaesthesia. Reserpine (1.0 mg/kg) injected subcutaneously 24 h before experiment. Record of salivary secretion from the submaxillary gland (top), mean arterial pressure (middle) and venous outflow (bottom). Stimulation of the chorda tympani (C) and the cervical sympathetic (S) with supramaximal pulses (20 V; 0.5 msec; 10/sec; 60 sec). At first arrow atropine (0.5 mg/kg i.v.), at second arrow guanethidine (10 mg/kg i.v.). Note: the initial potentiation of the vasodilatation by atropine and its reduction by guanethidine; prior treatment with reserpine does not alter the secretory and vasodilator effects of chorda stimulation

In cats treated with reserpine (1 mg/kg) 24 h previously an essentially normal vasodilatation and salivary response were evoked by stimulation of the chorda tympani nerve despite the fact that the effects of sympathetic stimulation were abolished (Fig. 3). Similarly a normal vasodilatation and increase in the rate of secretion of saliva accompanied chorda stimulation in the submaxillary glands of cats from which the ipsilateral superior cervical ganglion had been removed 14–21 days before the acute experiment.

It would therefore seem that an adrenergic mechanism is not involved in the atropine-resistant vasodilatation in the submaxillary gland of the cat. The effects of adrenergic neurone-blocking agents on the responses to chorda stimulation are probably related to their antagonistic effects on cholinergic ganglionic transmission<sup>8</sup>. However, the abolition by adrenergic neurone-blocking agents of the after-vasodilatation which follows sympathetic stimulation would appear to be a result of their effects on adrenergic transmission, since this after-vasodilatation is also abolished by the  $\beta$ -adrenergic receptor blocking agent pronethalol (Fig. 4). These observations suggest that the vasodilatation which follows sympathetic stimulation is caused by the sympathetic transmitter stimulating vascular  $\beta$ -receptors and is not due to the formation of bradykinin as suggested by Hilton and Lewis.

Small specimens of cat submaxillary salivary gland and the chorda tympani nerve were freeze-dried, treated with formaldehyde gas, embedded in paraffin wax, sectioned (8–10  $\mu$ ), and mounted for fluorescence microscopy<sup>9</sup>. In addition, portions of

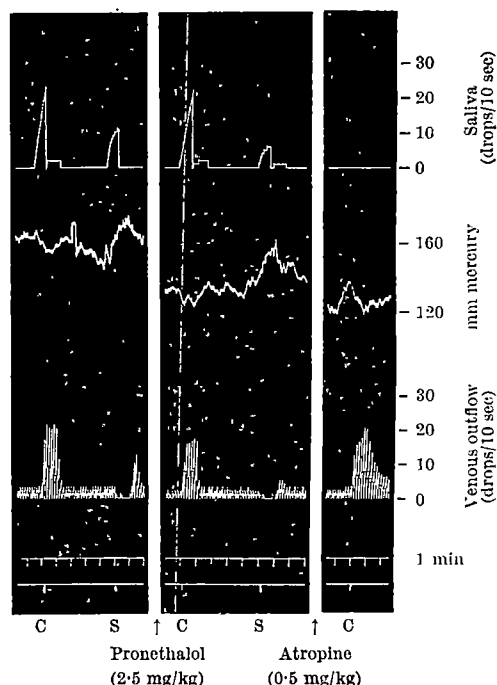

Fig. 4. Cat, 3.5 kg, ♂. Chloralose anaesthesia. Record of salivary secretion from the submaxillary gland (top), mean arterial pressure (middle) and venous outflow (bottom). Stimulation of the chorda tympani (C) and the cervical sympathetic (S) with supramaximal pulses (20 V; 0.5 msec; 10/sec; 60 sec). At first arrow pronethalol (2.5 mg/kg i.v.), at second arrow atropine (0.5 mg/kg i.v.). Note: Pronethalol antagonizes the after-vasodilatation which followed sympathetic stimulation

Fig. 5. Fluorescent adrenergic nerve fibres in cat submaxillary salivary gland. ( $\times 250$ )

Fig. 6. Collections of ganglion cells in the core of the cat chorda tympani nerve (haematoxylin and eosin;  $\times 250$ )

salivary gland and nerve were fixed in Orth's fluid and unstained sections were examined for chromaffin tissue.

No chromaffin tissue was found either in the chorda tympani or in the salivary gland. In the salivary gland a network of fine fibres which had an intense yellow-green fluorescence was found, surrounding the mucous alveoli (Fig. 5). No fluorescent nerve cells were seen although groups of non-fluorescent ganglion cells were seen within connective tissue bands.

No fluorescent adrenergic fibres or ganglion cells were found in serial sections of the chorda tympani. Typical adrenergic fluorescent fibres were seen surrounding blood vessels in the epineurium.

After examination in the fluorescence microscope paraffin was removed with xylene and the sections were stained with haematoxylin and eosin. Large collections of ganglion cells were found in the core of the chorda tympani nerve (Fig. 6).

In conclusion it may be said that although the vasodilatation evoked by chorda stimulation is abolished by adrenergic neurone-blocking agents, the underlying

physiological mechanism is not adrenergic. However, an adrenergic mechanism and not a plasma kinin would appear to be responsible for the vasodilatation which follows sympathetic stimulation. Finally, we should like to suggest that the pain in the region of the salivary glands experienced by patients treated with bretylium may well be ischaemic in origin, and not the result of an excessive hyperaemia as suggested by Emmelin and Engström. A reduction in the functional hyperaemia in association with a meal could result in a shortage of oxygen with ischaemic pain. The increase in gland cell activity induced by bretylium would further contribute to the oxygen deficiency.

## ELECTRON MICROGRAPHY OF ANTIBODY-PRODUCING CELLS

By DR. A. E. BUSSARD and DR. J. L. BINET

Institut Pasteur and Centre de Transfusion Sanguine, Paris

INVESTIGATIONS on the identification of antibody-producing cells have made use of immuno-fluorescent histological techniques<sup>1</sup> and of microdrop isolation techniques<sup>2,3</sup>. In the first method, identification usually relies on the antigenic properties of the antibody molecules produced by the cell and not on their antibody activity<sup>4,5</sup>. In the second method there is no ambiguity about the antibody-synthesizing capacity of the cells. Both methods, however, are based on optical microscopy.

Electron microscopy was recently applied to the investigation of immunocytes (antibody-producing cells) using the ferritin technique<sup>6,7</sup>. Identification of the immunocytes based on their capacity to fix ferritin-tagged antigen is not unequivocal because of a considerable amount of non-specific fixation of ferritin by reticulo-endothelial cells.

The introduction of the method of localized haemolysis in gel (LHG) by Ingraham and Bussard<sup>8,9</sup>, and by Jerne and Nordin<sup>10</sup> has provided a means by which the cell producing antibody can be identified without any doubt. The morphology of the antibody-producing cell can be examined by any kind of microscopic examination.

The production of anti-sheep erythrocyte (SE) haemolysis by lymph-node cells of immunized rabbits, in a physiological gel, has been investigated by the method described by Ingraham and Bussard. Minor modifications of the gel method have been introduced, enabling the antibody-producing cells to be examined with the electron microscope.

Popliteal lymph-node cells of adult rabbits in a stage of secondary reaction (4 days after booster injection of SE in the foot-pad) were prepared and counted for viability by the trypan blue exclusion method (see ref. 9).

Preparations for electron microscopy were made only when the population of the lymph-node cells had an activity greater than 200 active cells/million viable cells. Suspension of the active lymph-node cells ( $10^7$ /ml.) were added to carboxy-methoxy-cellulose gel, containing SE ( $5 \times 10^9$ /ml.) and guinea-pig complement as previously described<sup>9</sup>. When the activity of the lymph-node cell suspension was very high a concentration of  $10^6$  lymph-node cells/ml. was used. This measure increased the probability of finding only one lymph-node cell in each zone of haemolysis. A small amount of the gel containing

cells (0.1 ml.) was pipetted into the bottom of a glass tube (10 mm diameter) and incubated at 37° for 2 h. When an aliquot preparation, on a microscope slide, showed that the number of plaques of haemolysis had reached its maximum, Palade fixative was layered on the bottom of the tube on top of the gel. After 30 min of fixation, the osmic acid was removed and the pellet washed, dehydrated and finally embedded in 'Epon'.

The pellet of dehydrated gel was removed by breaking the tube and then fixed on a Porter-Blum microtome. The whole pellet was cut in serial sections—thick ones at first (1 $\mu$ ) for observation with the optical microscope, until the boundary of a zone of haemolysis was reached; then thin sections (200–300 Å units) were made for electron microscopy. After cutting through the lymph-node cells, thick sections were made again so long as no leucocyte was found. As soon as a thick cut showed the presence of a leucocyte as seen by phase-contrast microscopic examination, thin cuts were resumed through the cutting of the leucocyte. By such a technique a whole series of haemolysis zones were completely examined without losing a section of the preparation and we were able to observe and photograph all the cells present in each zone of haemolysis.

In our attempts to obtain serial sections through zones of haemolysis containing only one or two white cells, we were successful in twelve cases. Only those haemolytic zones in which all sections could be examined have been included in our results.

(a) The haemolytic zones in which all the red blood cells have lost their haemoglobin and have become ghosts are as easy to recognize with the phase-contrast, as with the electron, microscope. These zones have a characteristic appearance which is constant from one experiment to another. Although the size of the haemolytic zone may vary from one experiment to the next, in any one experiment their size is similar. In cross-section the zones are round with a diameter of 70–120 $\mu$  (Fig. 1). The volume of the zone varies with the activity of the cells and the duration of the incubation.

Fig. 1. Phase-contrast micrograph of a zone of haemolysis with the antibody-producing cell in the centre

All the dimensions and the shape of the zones can be determined from the known shape and thickness of the sections and the total number of sections in the zone. The haemolytic zones are not spherical but elliptical, with their long axes lying along the length of the tube. This flattening occurs not only in the zone as a whole but also in the individual cells in the zone. Thus, the plasma cells are 15–20 $\mu$  long and are not more than 3 $\mu$  thick.

(b) The type of white cells found in the haemolytic zone have been determined. In all cases plasma cells have been found. These are readily identified with the phase-contrast microscope (Fig. 1) and by their large content of ergastoplasm as seen in the electron microscope

Fig. 2. a, Phase-contrast micrograph of a zone of haemolysis with a plasma cell in the centre; b, electron micrograph of the plasma cell from the centre of the zone shown in a

(Fig. 2b). In seven out of twelve cases plasma cells were isolated in the centre of the haemolytic zone (Fig. 2a); in a single case two plasma cells were found. In each of two other zones a lysed white cell was found which resembled plasma cells under phase contrast but which could not be identified in the electron microscope. Finally, in each of two other zones a lymphocyte (Fig. 3c) in addition to a plasma cell (Fig. 3b) was found. One of the lymphocytes had a very well-developed centriole.

(c) The appearance of the plasma cells in the electron microscope was not unusual. Inclusions could not be discerned in their nuclei. Many dilated ergatoplasmic sacs were seen in the cytoplasm (Fig. 2b). A dense electron-opaque material close to the Russell bodies could be seen between the ergatoplasmic sac surfaces. Frequently, haemolysed red blood cells were found adhering

Fig. 3. *a*, Phase-contrast micrograph of a zone containing two lymph-node cells at different locations in the plaque; *b*, electron micrograph of the plasma cell from the centre of the zone; *c*, electron micrograph of the lymphocyte slightly peripheral in position

to the cytoplasmic membrane. Occasionally, openings in the cytoplasmic membrane were seen at the site of attachment of the red blood cells; it is, however, difficult to ascribe a function to the openings. Most of the haemolysed red blood cells were not in contact with the plasma cell and sometimes red blood cells which were not haemolysed were found adhering to the plasma cell.

(*d*) It was found by sucrose gradient ultracentrifugation<sup>14</sup> that most of the haemolytic antibody in rabbit serum was of the 19 *S* type. However, some samples of serum contained appreciable amounts of 7 *S* haemolysin (as much as 20 per cent). Thus, not all haemolysin is of the 19 *S* form, at least in the rabbit in a secondary phase of immune response.

Mercapto-ethanol (0.1 M-30 min at 37° C) completely inhibited the haemolytic activity of all samples of serum

including those containing 7 *S* antibody. Thus, mercapto-ethanol inhibition of an antibody activity cannot be used as a specific proof that the antibody involved is of the 19 *S* type.

Several points merit discussion: characteristics of true haemolytic zones as seen by the electron microscope; the differences between true haemolytic zones and artefacts; evidence that the lymph-node cell is responsible for the formation of the haemolytic zone and that the haemolysin is synthesized *de novo* in the gel; the nature of the responsible cell; the type of antibody synthesized and its relation with the cytological type of the active white cell.

(1) In the preparations devised for work with the electron microscope the shape of the lytic zone is different from that obtained under a cover-slip on a glass slide. The placing of a thin layer of gel near the bottom of a test-tube for electron microscopy results in a haemolytic zone of ellipsoidal shape the long axis of which is parallel to the long axis of the tube. The ellipsoid is flattened by the process of dehydration, necessary for viewing in the electron microscope. A lymph-node cell is always found at the centre of the zone of haemolysis. In a given plaque practically all the red blood cells are lysed, with the occasional exception of some red blood cells which are adherent to the lymph-node cell.

Haemolytic zones formed by a white cell are easy to distinguish from artefactual clear areas. In the latter there are no red blood cells or ghosts or there may be extensive agglutination with only slight partial haemolysis of red cells. Further, white cells are not found in the centres of these areas.

(2) Earlier work<sup>8,9</sup> supports the conclusion that the lymph-node cell is responsible for the localized haemolysis. Briefly the evidence is: only cells from immunized animals give rise to the zones—the number of haemolytic plaques is proportional to the number of lymph-node cells in the preparation—and at the centre of every plaque there is only one lymph-node cell. There is good evidence that haemolysis is due to antibody newly synthesized by the cells in the gel and not simply to the diffusion of pre-formed antibody since the formation of the haemolytic zone is markedly reduced by dinitrophenol, actinomycin and puromycin<sup>9</sup>. The cells in the haemolytic zones have a well-developed endoplasmic reticulum which is known to be associated with protein synthesis.

(3) Since, in almost all cases, a single plasma cell was found at the centre of the haemolytic plaque, one can conclude that it is at least one of the types of cell which produces haemolysin. In the plaque with one plasma cell and one lymphocyte it is not possible to say which cell was the haemolysin producer. Since we did not find plaques with only a lymphocyte present we cannot say whether they are capable of haemolysin synthesis.

(4) The haemolytic antibody found in the serum of the immunized rabbits from which the lymph-node cells were derived was of the 19 *S* type. This was shown by ultracentrifugation in sucrose gradient<sup>14</sup>. If we assume that in our case the essential producers of these 19 *S* antibodies were the lymph nodes, then we may conclude that the lymph-node cells in the plaques observed with the electron microscope were 19 *S* producers. In the work of de Petris, electron microscopy was applied to the examination of cells producing anti-ferritin in hyper-immune animals<sup>6</sup> and it is most probable that these cells were synthesizing 7 *S*-type antibodies in contrast to the cells in our investigations which formed mainly 19 *S* antibodies.

Synthesis of 19 *S*  $\gamma$ -globulin in pathological cases, such as the Waldenström disease in man, has been ascribed to the lymphocytic cell<sup>5,11,12</sup>. Identification of the antibody-producing cell has been made, in these macroglobulinaemia cases, by immuno-fluorescence histology<sup>13</sup>. These cells have been described as "large- and medium-sized lymphocytes and lymphoblasts". However, it is possible that with further characterization under the electron micro-

scope they might be considered plasma cell intermediates with well-developed endoplasmic reticulum.

We thank Dr. Bessis for his interest and help, and Mr. J. C. Mazie and Mlle. Vinzens for their assistance.

## COMPARATIVE EFFECTIVENESS OF ADENOSINE ANALOGUES AS INHIBITORS OF BLOOD-PLATELET AGGREGATION AND AS VASODILATORS IN MAN

By PROF. G. V. R. BORN, DR. R. J. HASLAM and Miss MIRYAM GOLDMAN

Department of Pharmacology, Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C.2

AND

DR. R. D. LOWE

Department of Medicine, St. Thomas's Hospital Medical School, London, S.E.1

THERE is increasing evidence that the aggregation of blood platelets brought about by adenosine diphosphate (ADP) is involved in haemostasis and in thrombogenesis<sup>1-6</sup>. This aggregation can be inhibited by substances related to ADP<sup>7</sup>, particularly by adenosine and by some of its analogues<sup>3,8</sup> not only *in vitro* but also *in vivo*<sup>9,10</sup>. One analogue already known to have inhibitory activity greater than that of adenosine itself is 2-chloro-adenosine<sup>11</sup>. We have now found other substances related to adenosine which have inhibitory activity and we have investigated further the molecular structure required for this inhibition. Adenosine and several of its derivatives are known to be vasodilators<sup>12,13</sup>. We show here also that the relative potency of some of these substances in inhibiting platelet aggregation corresponds with their relative potency as vasodilators.

Platelet aggregation and its inhibition were measured by a turbidimetric method already described<sup>14</sup>. Two different models of the apparatus were used<sup>6,7</sup> and the results agreed satisfactorily. Human platelet-rich plasma containing 0.1 volume of 3.8 per cent (w/v) trisodium citrate was incubated at 37° C and stirred at 1,000 r.p.m. The compound to be tested for inhibitory activity, dissolved in 0.154 M saline, was added after 3 min. Five minutes later a solution of ADP in saline was added to give a standard concentration, usually  $5 \times 10^{-6}$  M. Aggregation of platelets was measured by the 'rate' and 'extent' of the decrease in optical density of the platelet-rich plasma. Inhibitory activity was indicated by diminutions in these parameters of aggregation. With each compound, the inhibitory activities of different concentrations were compared with that of a standard concentration of adenosine, usually  $2 \times 10^{-5}$  M. The inhibitory activity of each compound was expressed as a percentage of that of adenosine, that is:

$$\frac{\text{concentration of adenosine selected for the comparison}}{\text{concentration of inhibitor required to produce the same inhibition as the chosen concentration of adenosine}} \times 100$$

As contamination of the compounds with adenosine could give a false indication of inhibitory activity, those with more than 10 per cent of the activity of adenosine were examined for such contamination by subjecting them to ascending chromatography on Whatman No. 4 paper using *n*-butanol : acetic acid : water (12 : 3 : 5 by volume)

as solvent. This system separated these compounds except 2-aza-adenosine, from adenosine.

The results are shown in Table 1. Only a few compounds had inhibitory activity comparable with that of adenosine. We confirmed that its activity was exceeded only by 2-chloro-adenosine<sup>11</sup>. Some other derivatives substituted in position 2 had activity approaching that of adenosine, notably 2-bromo- and 2-fluoro-adenosine. 2-Aza-adenosine and adenosine-1-*N*-oxide also inhibited quite strongly, showing that alterations of the molecule in this region are less critical than elsewhere. Thus, inhibitory activity was markedly diminished by almost any other modification (see also ref. 8), for example, substitution in or replacement of the 6-amino group; alterations in the purine ring except 2-aza-adenosine; substitution of the ribosyl moiety in other positions; and replacement of ribose by some other sugars. Certain alterations of the ribosyl moiety, notably removal of the oxygen in position 3', or substitution of phosphate in position 5' or at both 2' and 5', left up to 10 per cent of the activity, while others, such as substitution of sulphate at position 5', abolished activity altogether. It is interesting that two of the compounds which inhibited aggregation, 3'-deoxyadenosine and adenosine-1-*N*-oxide, cause platelet aggregation as the 5'-diphosphates<sup>15</sup>.

Thus inhibitory activity requires a highly specific molecular structure. The specificity is indicated also by the fact that the most potent compounds inhibited aggregation in concentrations of the same order as the concentration of ADP causing aggregation. In this respect, inhibition by adenosine analogues differs from inhibition caused by certain anti-histamines and local anaesthetics<sup>16</sup> and by esters of certain amino-acids<sup>17</sup>. The high specificity of the adenosine inhibitors implies a correspondingly specific receptor. The chemical nature of this receptor is still unknown.

Vasodilator activity was measured in the human forearm by venous occlusion plethysmography using mercury-in-rubber strain-gauges; the hand was excluded by a wrist cuff inflated to a pressure of 250 mm mercury. Sterile saline was infused continuously through a needle inserted into one brachial artery; this infusion caused no significant change in blood flow. Flow was also measured in the other forearm as control. Seven compounds with widely differing activities as inhibitors of platelet aggregation were chosen for comparison with adenosine as vasodilators.

Table 1. ACTIVITY OF COMPOUNDS RELATED TO ADENOSINE AS INHIBITORS OF AGGREGATION OF HUMAN PLATELETS BY ADP

	Activity relative to adenosine (per cent)	Chromatographic purity (per cent)	Source of compound
2-Substituted adenosines			
* 2-Chloro-adenosine	> 150 < 300	> 95	Dr. J. A. Montgomery, Southern Res. Inst., Birmingham, Alabama
2-Bromo-adenosine	> 50 < 100	> 95	
2-Fluoro-adenosine	> 30 < 60	> 95	Dr. G. B. Brown, Sloan-Kettering Inst. of Cancer Res., Rye, N.Y.
2-Methylthio-adenosine	> 10 < 25	> 95	Dr. E. Fitzgibbon, Southern Res. Inst., Birmingham, Alabama
2-Acetamido-adenosine	5	< 5	
* 2-Hydroxy-adenosine (isoguanosine; erotenoside)	< 1	—	
* 2-Amino-adenosine (2,6-diaminopurine riboside)	< 1	—	
6-Substituted purine-9- $\beta$ -D-ribofuranosides			
6-Dimethylaminopurine riboside (that is, N <sup>6</sup> ,N <sup>6</sup> -Dimethyladenosine)	> 5 < 10	—	Dr. K. Burton, M.R.C. Unit for Research into Cell Metabolism, Oxford
6-Furfurylamino-adenosine (that is, N <sup>6</sup> -Furfuryladenosine)	< 10	—	Zellstoffabrik Waldhof, Mannheim, Germany
6-Chloropurine riboside	< 10	—	
6-Methylthiopurine riboside	< 5	—	Dr. J. A. Montgomery (see above)
6-Hydrazinopurine riboside	< 5	—	Dr. A. D. Welch, Yale Univ. School of Med., Conn.
6-Hydroxylaminopurine riboside	< 5	—	
Substitution of and in the ribosyl moiety of adenosine			
Adenosine 2', (3'), 5'diphosphate	> 5 < 20	> 95	Dr. A. D. Welch (see above)
* Adenosine-5'-monophosphate	10	> 95	Böhringer und Sohne, G.m.b.H., Mannheim, Germany
Adenosine-3'-monophosphate	< 4	—	Prof. Kunio Yagi, Nagoya Univ., Japan
Adenosine-5'-monosulphate	< 5	—	I.C.I., Ltd., Pharmaceuticals Div., Alderley Park, Cheshire
3'-Deoxy-adenosine ('Cordycepin')	> 5 < 10	> 95	California Corporation for Biochemical Res., Los Angeles
* 2'-Deoxy-adenosine	< 1	—	Zellstoffabrik Waldhof (see above)
2',3'-O-isopropylidene adenosine	< 10	—	I.C.I., Ltd., Pharmaceuticals Div. (see above)
Adenosine-9- $\beta$ -D-mannopyranoside	< 4	—	Dr. E. J. Reist, Stanford Res. Inst., Menlo Park, California
Adenosine-9- $\beta$ -D-arabinofuranoside	< 2.5	—	Dr. J. A. Montgomery (see above)
<i>Cis</i> -3-(6-amino-9H-purin-9-yl) cyclopentanemethanol	< 6	—	
Other adenosine derivatives			
Adenosine-1-N-oxide	> 15 < 30	> 95	Dr. G. B. Brown (see above)
6,2',3',5'-Tetra-acetyladenosine	< 5	—	Zellstoffabrik Waldhof (see above)
Substitution of the ribosyl moiety of adenosine at other positions on the purine nucleus			
Adenosine-7- $\beta$ -D-ribofuranoside	< 5	—	Dr. J. A. Montgomery (see above)
Adenosine-3- $\beta$ -D-ribofuranoside	< 5	—	Dr. Hogenkamp, Dept. of Biochem., Iowa State Univ.
Modification of the purine ring in adenosine			
2-Aza-adenosine	> 40 < 100	—	Dr. G. B. Brown (see above)
4-Amino-7-D-ribofuranosyl-pyrrolo[2,3-d]pyrimidine (tubercidin)	< 5	—	Dr. A. D. Welch (see above)
4-Amino-1-D-ribofuranosyl-pyrazolo[3,4-d]pyrimidine	< 5	—	I.C.I., Ltd., Pharmaceuticals Div. (see above)

\* The effects of these compounds have been described in earlier publications<sup>8,11</sup>, but are included here to give a more complete picture.  
 < Indicates no detectable inhibition by the highest concentration tested.

The compounds were dissolved in saline and sterilized by autoclaving at 115° C for 30 min. Two ml. of solution was injected into the brachial artery in 6–7 sec. Since some compounds were available only in small quantities we were unable to compare the concentrations required to produce a given response, as was done when comparing their effects on platelet aggregation. Instead, the effect of a given dose of each compound was compared with that of the same dose of adenosine on the basis of the time integral of blood flow (see Fig. 1).

Table 2 shows that the relative activities of the compounds were the same in causing vasodilatation as in inhibiting platelet aggregation, with one exception. This was 2-methylthio-adenosine which, because of its low solubility, was injected in such low concentrations that

Fig. 1. Effect on forearm blood-flow of rapid injections of adenosine and analogues, each in 2 ml. saline. The sequence of injections was, from left to right: 2-chloro-adenosine, 2-bromo-adenosine, and 2-aza-adenosine each at  $2.5 \times 10^{-4}$  M; followed by 6-chloropurine riboside, adenine-9- $\beta$ -D-mannopyranoside 3'-deoxyadenosine and adenosine, each at  $8 \times 10^{-4}$  M.

Table 2

Compound	No. of experiments	Response to compound	Response to adenosine	Mean
2-Chloro-adenosine	3	105	180	270
2-Aza-adenosine	4	71	66	72
2-Bromo-adenosine	3	88	54	55
3'-Deoxy-adenosine	3	11	0	0
2-Methylthio-adenosine	3	4	0	0
6-Chloropurine riboside	3	0	0	0
Adenosine-9- $\beta$ -D-mannopyranoside	3	0	0	0

The response of forearm blood flow to injection of adenosine analogues is compared with the response to the same dose of adenosine (results from 9 subjects). The response is expressed as the area under the curve of blood flow against time.

reliable measurements of its effect were not possible. The two compounds which had no activity against platelet aggregation also had no detectable vasodilator activity even when injected at a concentration of  $3 \times 10^{-3}$  M. The large increases in forearm blood flow which were produced by the active compounds were not accompanied by flushing of the skin, indicating that the vasodilatation was in the muscles. The four most potent compounds, particularly 2-chloro-adenosine, caused pain in the forearm. When adenosine was infused an initial large increase in blood flow was followed by a decrease to a new rate which was still higher than the control (Fig. 2).

The results show that, among adenosine analogues, the structure/activity relationships for the inhibition of platelet aggregation and for vasodilatation are similar in man. Calculation shows that vasodilatation was produced by adenosine in blood concentrations as low as  $1-5 \times 10^{-4}$  M, which is similar to the concentration that inhibits platelet aggregation. These facts suggest

Fig. 2. Effect on forearm blood flow of an intra-arterial infusion of adenosine ( $5 \times 10^{-4}$  M) at a rate of 1.0 ml./min for 4 min (indicated by the black line)

that the effects of the adenosine analogues on platelet aggregation and on vascular smooth muscle are mediated by similar receptors. An implication of this is that other related compounds which may be found to inhibit platelet aggregation may also cause vasodilatation. In

the cat, adenosine and some of its analogues cause hypotension<sup>12</sup>. If effective inhibitors of platelet aggregation of the adenosine type also cause hypotension in man, this may complicate any attempt to use them therapeutically in thrombotic diseases.

We wish to thank those named in Table 1 who supplied compounds, and the volunteer blood donors. We thank the Life Insurance Medical Research Fund of the United States, the Medical Research Council (G. V. R. B.) and Imperial Chemical Industries, Ltd., Pharmaceuticals Division (R. J. H. and M. G.), for financial support.

## A MODEL PREDICTING CHARACTERISTICS OF GENETIC MAPS IN *Neurospora crassa*

By MARY B. MITCHELL

Division of Biology, California Institute of Technology, Pasadena

**R**ESTRICTION of recombinant frequencies to an intermittent series was suggested by the unexpected recurrence of certain values observed among random ascospore isolates from crosses of linked markers<sup>1,2</sup>. The suggestion has been strengthened by recognition, in large samples of spore octets from individual asci, of a recurring ratio, approximately 9:1:8, of octets which are non-recombinant (parental ditype, PD), totally recombinant (non-parental ditype, NPD) or half recombinant (tetra-type, T) (ref. 3). This ratio may be used as a basis for calculating a series in which the degree of linkage rises by steps that reproduce recombinant frequencies indicated as recurrent ones by random spore data. To obtain the first member of the series, 9:1:8, a basic ratio, 1:1:4, indicating no linkage, is adjusted as follows: PD  $\times$  4.5; NPD  $\times$  0.5; T unchanged. For the next member, the correction of the basic ratio is PD  $\times$  9, NPD  $\times$  0.25, and so on.

In order to illustrate the applicability of this series to spore octet data, the distribution patterns of individual markers, in linear asci, must be taken into account. A marker showing regular 4m:4+ segregation may be distributed by fours in two ways (simple patterns) or by pairs in four ways (complex patterns). Equal frequencies of the six patterns will, of course, give an S:C ratio of 1:2 but this ratio is not uniformly observed. Often S exceeds C. To account for this, present theory assumes that the division products of the two centromeres of a chromosome pair are regularly distributed by fours, following meiosis in the ascus, and that crossing over between the centromere and a marker locus allows pair-wise distribution of the marker<sup>4</sup>. Thus the S:C ratio is taken as a measure of the degree of linkage, or the map distance, between the centromere and the marker locus.

On the basis of the definition of linkage used here, namely, a significant deviation from a 1:1 ratio of recombinant to non-recombinant classes for any given pair of markers, recent findings are in agreement with the idea that S:C ratios greater than 1:2 reflect linkage, since these ratios, like recombinant frequencies, appear to form a discontinuous series. Observed values suggest 1:1, 2:1, 4:1, 8:1, etc. A series of ratios, not easily distinguishable from these experimentally, may be obtained through application of the linkage correction factors given here, with the assumption that there are two basic ratios, N:0 and 1:2, and that intermediate values reflect different degrees of linkage either directly or indirectly. To illustrate, a cross involving markers *a*, S:C = N:0, and *b*, S:C = 1:2, gives, with no linkage, three of the seven phenotype distribution classes characteristic of two-marker crosses, PD1 and NPD1 (*a* and *b* simple) and T1 (*a* simple, *b* complex), in a ratio of 1:1:4. First-degree linkage between *a* and *b* will change the class ratio to 9:1:8 and the apparent S:C ratio of *b* to 10:8. Successively higher degrees of linkage will give apparent ratios of 37:16, 145:32, 577:64, etc. If *a* is assumed to represent markers which affect the phenotype inconspicuously, then intermittent S:C ratios will be expected from, apparently, single marker crosses. (It is not necessary to assume that all S:C = N:0 markers are inconspicuous.) Since the degree of linkage between *b* and a given *a* may differ from strain to strain and also since different strains may reasonably be assumed to sometimes carry different *a*-type markers, the model predicts the changes in S:C ratios often observed from single marker crosses when markers are re-isolated or crossed to different *m*<sup>+</sup> parents<sup>5</sup>. Observed ratios which do not coincide with any member of the above series may be attributed to indirect linkage, to be considered below, or to non-

uniformity of fruiting bodies within a cross<sup>3</sup>. Common occurrence of the latter situation would have escaped recognition because of experimental difficulties involved in the serial isolation of sufficiently large numbers of spore octets from individual fruiting bodies.

Introduction of additional conspicuous markers allows prediction of phenotype distribution class frequencies observed from more complex crosses, as shown in Table 1. For the first cross,  $c + cot \times + col +$ , the linkages assumed are as follows: fourth-degree linkage of  $c$ ,  $S : C = 1 : 2$ , to  $a-1$ , inconspicuous,  $S : C = N : 0$ , giving the expected  $S : C$  ratio for  $c$  as 577 : 64; 2nd degree linkage of  $col$ ,  $S : C = 1 : 2$ , to  $a-2$ , also  $N : 0$ , inconspicuous, hence  $col$  is given an expected  $S : C$  ratio of 37 : 16; no direct linkage of  $cot$ ,  $S : C = 1 : 2$ , to an  $N : 0$  factor but first-degree linkage between  $col$  and  $cot$ , thus the expected  $S : C$  ratio for  $cot$ , reflecting its indirect linkage to  $a-2$ , becomes, approximately, 1 : 1.2. For the  $c, col$  combination, expected relative frequencies of the phenotype distribution classes are calculated in the following way:

$$\begin{aligned} PD1 + NPD1 &= S c \times S col / S + C c \times S + C col \\ T1 &= S c \times C col / S + C c \times S + C col \\ T2 &= C c \times S col / S + C c \times S + C col \\ T3 + PD2 + NPD2 &= C c \times C col / S + C c \times S + C col \end{aligned}$$

Since  $c$  and  $col$  are unlinked, the PD1 and NPD1 classes are expected to be equally frequent. The last three classes are distributed on the basis of equality of PD and NPD plus the common-sense one that T3, which is half recombinant and half non-recombinant, will be twice as frequent as either PD2, totally non-recombinant, or NPD2,

Fig. 1. Comparison of the distribution of observed recombinant frequencies, given in Table 2, with that of frequencies calculated for all combinations of the  $S : C$  ratios, 1 : 2, 5 : 4, 37 : 16, 145 : 32, 577 : 64, with five degrees of linkage for each combination. Lengths of the horizontal bars indicate the number of occurrences, 1-6, of each frequency.

Table 1. FREQUENCIES OF PAIR-WISE PHENOTYPE DISTRIBUTION CLASSES FROM THREE-MARKER CROSSES

Cross 1, $c + cot \times + col +$

PD2	12	11.2	26	29.2	10	9.8
NPD2	1	1.2	1	2.2	1	2.3

Expected frequencies are calculated on the basis of first-degree linkage between  $col, cot$  and  $cot, dn$  and with the following  $S : C$  ratios assumed:  $c$ , 577 : 64;  $col$ , 37 : 16;  $cot$  and  $dn$ , 1 : 2. Observed frequencies of the three-marker distribution classes are given elsewhere<sup>1,4</sup>.

totally recombinant. Expected relative frequencies for  $col, cot$  without linkage may be calculated similarly and the correction for first-degree linkage then applied as follows:  $PD \times 4.5$ ;  $NPD \times 0.5$ . Expected values for  $c, cot$  are obtained in a more complicated way, from expected frequencies of the 29 three-marker distribution classes, as described in detail elsewhere<sup>3</sup>. Briefly, expected values for the  $c, col$  pair-wise combinations are distributed according to expected relative frequencies, with first-degree linkage, of the corresponding  $col, cot$  combinations. In the few cases in which three-marker classes differ only with respect to  $c, cot$  combinations, distribution can be made on the basis of the general conclusions that in the absence of linkage  $PD = NPD$  and  $T3 = PD2 + NPD2$ .

The second cross shown in Table 1,  $col cot dn \times + + +$ , is of interest, even though the sample is small, because it formed the basis of a map of linkage group IV published some years ago<sup>6</sup>. Expected frequencies were calculated with the following assumptions: 2nd degree linkage of  $col$ ,  $S : C = 1 : 2$ , to  $a$ , inconspicuous,  $S : C = N : 0$ , but no direct linkage between  $a$  and  $cot$  or  $dn$ , both  $S : C = 1 : 2$ ; first-degree linkage for  $col, cot$  and  $cot, dn$  but no direct  $col, dn$  linkage. Frequencies of the 29 three-marker classes were obtained by first calculating values for the  $col, cot$  pair-wise combinations directly and then distributing these, as outlined here, according to expected relative frequencies of the corresponding  $cot, dn$  combinations, with the assumptions of first-degree  $cot, dn$  linkage and no direct  $col, dn$  linkage. Expected frequencies of  $cot, dn$  and  $col, dn$  pair-wise combinations were then obtained by adding the appropriate three-marker classes. Direct  $a, col$  linkage gives the expected  $S : C$  ratio of  $col$  as 37 : 16. Indirect linkage of  $cot$  and  $dn$  to  $a$  gives expected ratios of approximately 1 : 1.2 and 1 : 1.7 for these two markers. Indirect linkage between  $col$  and  $dn$  gives a recombinant frequency which is somewhat less than the sum of the  $col, cot$  and  $cot, dn$  frequencies. The expectations are 27.8 per cent for  $col, cot$  and  $cot, dn$  and 40.2 per cent for  $col, dn$ . Thus a satisfactory 'linear map' is obtained showing the order, 'centromere'— $col$ — $cot$ — $dn$ .

In order to make a more general comparison between calculated and observed recombinant frequencies, expected frequencies of one of the two recombinant classes among random spores were calculated for all pair-wise combinations of the  $S : C$  ratios, 1 : 2, 5 : 4, 37 : 16, 145 : 32, and 577 : 64, with five degrees of linkage for each combination. These are plotted in Fig. 1 with frequencies of the ++ recombinant class observed from the two-marker crosses

listed in Table 2. The observed values represent direct counts, not estimates, made under essentially uniform conditions by the same observer (myself). All such data at hand are included if linkage is indicated and if the count of the recombinant class = 25 or more. A rough

\* If frequencies from two or more crosses involving different reisolates of the same mutants differ by less than 2 per cent, only the value from the largest sample is plotted in Fig. 1.

† Isolate 38502 is a double mutant the closely linked components of which are *pyr-2* and *dn*; 28815 is also a double mutant, *ad lys*, the *lys* component being the one used here.

‡ The symbol (cot) preceding a reisolate number indicates that the temperature-sensitive marker, *cot*, was present but unexpressed at the temperature of incubation used.

correspondence in overall distribution is apparent even though the calculated values are restricted to the results of direct linkage, which is not necessarily true of the observed values. It is also apparent that if a system such as that under consideration were operating, one might expect to become aware, even from determinations on the modest scale presented, of recurring frequencies without being able to recognize sharp peaks.

Consideration of relative frequencies of spore octet classes in the same series of hypothetical two-marker-cross progenies allows a general prediction concerning mapping with respect to 'centromeres'. Briefly, the prediction is that directly linked markers, tested by pairs, will map on the same side of the 'centromere', if they give an unambiguous result in this respect. This reflects the effect of linkage in increasing the frequency of parental ditypes relative to that of tetratypes since one of the former classes, PD2, switches from a single to a double cross-over class while one of the latter, T2, does the reverse, when two markers are assigned to positions on opposite sides of the 'centromere'. If, on the other hand, two markers are assumed to be indirectly linked through linkage of both to the same inconspicuous marker,  $S:C = N:0$ , the expected result might well be interpreted as locating the 'centromere' between the two conspicuous markers. Such a situation may be illustrated with a hypothetical case in which two conspicuous markers, *b* and *c*,  $S:C = 1:2$ , show third- and second-degree linkage to *a*, inconspicuous,  $S:C = N:0$ . The three possible *a, b* classes, PD1, NPD1 and T1, occur in the ratio of 144:1:32. These values are distributed among the 11 three-marker classes according to the expected PD1:NPD1:T1 ratio, 36:1:16, for *a, c*. Expected relative frequencies of the *b, c* classes, all seven of which are represented, are then obtained by adding values for the appropriate three-marker classes and are, approximately, as follows: PD1, 51.8; NPD1, 1.8; T1, 23.2; T2, 11.8; T3, 2.6; PD2, 1.3; NPD2, 1.3. Thus the double cross-over classes, T3, PD2 and NPD2, are less frequent than either of the single cross-over classes, T1 and 2, and the result is consistent with the mapping of the 'centromere' between *b* and *c*. Since the situation involving indirect linkage appears, superficially at least, to be more exacting, one might expect that it would be observed less often than the result of direct linkage. This expectation would be in accord with an observed situation, namely, that, up to 1959, essentially all markers assigned to five of the seven linkage groups were mapped on the same side of their respective 'centromeres', despite the fact that cytologists have described all 'centromeres' as non-terminal<sup>10</sup>.

In conclusion it may be said that the proposed model, which is mainly an extrapolation from observations and does not include the assumption of a direct relationship between recombination maps and the spatial organization of genetic material, predicts observed situations which are unpredicted or ambiguous in terms of conventional theory. This result is thought to offer hope that adoption of a broader point of view in evaluating genetic data may be helpful in approaching a more complete understanding of mechanisms involved in the distribution of phenotypes in ascii and in recombination of linked markers.

## Occultation of Taurus-A by the Solar Corona at 430 Mc/s in June 1964

DURING June of every year, the radio source Taurus-A passes within a small angular distance of the Sun. This particular situation, commonly referred to as the occultation of Taurus-A by the Sun, permits an investigation of the Sun's outer corona as the radio source is viewed through it. The measurements made over the past several years have demonstrated that the radiation from the source is scattered at the electron density irregularities in the corona; as a result one observes an apparent broadening of the source accompanied by a decrease of its intensity. The effect becomes larger with decreasing angular separation of the source from the Sun. This phenomenon has been observed in the range of frequencies 26-178 Mc/s<sup>1-5</sup>. At wave-lengths of 6 and 18 cm the effect has been reported to be negative<sup>6,7</sup>, except that a positive result has been reported on 10- and 25-cm wave-lengths<sup>8</sup>. The results on all metre and decametre wave-lengths are consistent and are in accordance with the theory of small-angle multiple scattering, in which the angular size of the scattered distribution is proportional to the square of the wave-length. However, the increase of intensity on 169 Mc/s at  $7 R_0$  ( $R_0$  is the photospheric radius) from the centre of the Sun is not consistent with the theoretical prediction based on the lower frequency data<sup>5</sup>. In order to investigate if the coronal scattering is still effective at frequencies higher than 169 Mc/s, and in particular to see if the increase of intensity is also observed on 430 Mc/s, we undertook to observe at 430 Mc/s the occultation of Taurus-A by the solar corona in June 1964, using the 1,000-ft. dish of the Arecibo Ionospheric Observatory.

The 1,000-ft. dish has a half-power pencil beam of 9.5 arc at 430 Mc/s, and because of its large collecting area it is particularly suitable for studying the variation

Fig. 2. Relative intensity and apparent angular size of Taurus-A as a function of its angular separation from the Sun in solar radii. The short vertical lines indicate probable errors, including uncertainties in subtracting the solar contribution due to side lobes of the antenna.

of intensity of Taurus-A as its radiation passes through different regions of the corona. However, the beam has undesirable side lobes and special measurements had to be made to eliminate their effects.

The experimental procedure adopted was to have 5-6 drift curves, including the meridian drift of Taurus-A and 2-3 declination scans on each day observed. The receiver was calibrated for high-level operation, and a 1,000° K calibration signal was used. In addition, the radio source 3C123 was observed.

The Sun appeared to be relatively quiet, and fairly good data were obtained during the entire period of observation, including June 14 when the radiation from Taurus-A passed through the corona as close as  $5R_0$  from the Sun's centre. This was fortunate since there are not many data available at this distance.

The results are presented in Figs. 1 and 2. As can be seen from these results, no increase of intensity of Taurus-A was ever observed, in contrast to the result on 169 Mc/s<sup>4</sup>. On the contrary, a significant decrease of intensity was observed on June 13, 14, 15 and 16, the maximum decrease of about 20 per cent being observed on June 14 when the angular separation of Taurus-A relative to the Sun was about  $5R_0$ . On June 13, 15 and 16, the decrease was roughly 8 per cent. The declination scans show approximately the same intensities as the drift curves; the difference in intensity, if any, is no higher than the experimental uncertainties of removing the solar side lobe contribution. Because of the presence of side lobes in the records of Taurus-A, it is not easy to determine the change in its angular size. However, we seem to have observed a very small increase in size of about 1' arc on June 14. This small increase of angular size is in accord with the theoretical prediction if one extrapolates from lower frequency data on the assumption that the  $\lambda^2$  dependence of the angular extent of the scattered distribution holds down to 430 Mc/s. No change in position of the source was observed, indicating that the effect of refraction, if present, is small.

No difficulty was experienced in determining the base line of Taurus-A drift curves (or of declination scans) on

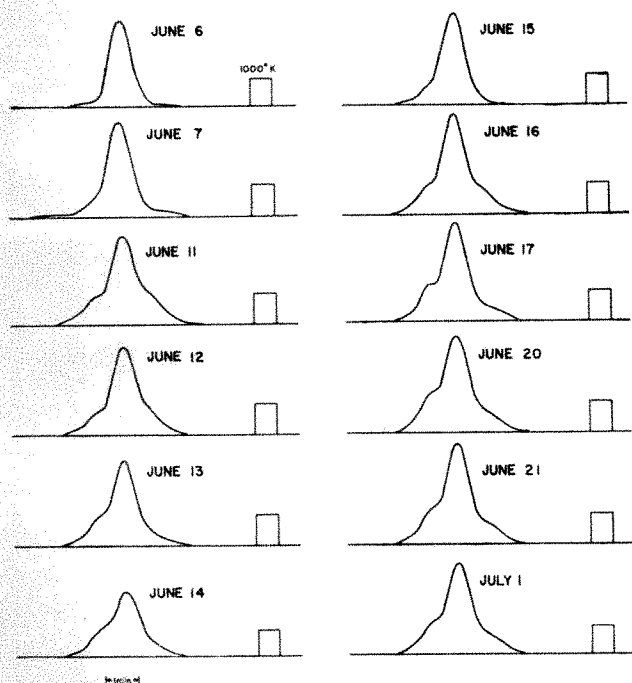

Fig. 1. Drift curves of Taurus-A near meridian transit, reconstructed after eliminating the solar contribution. The rectangular boxes on the right represent 1,000° K calibration signals.

any day except June 14, since the record of Taurus-A is situated on a rather flat portion of a side lobe due to the Sun. The situation is, however, different on June 14, when the right ascension of Taurus-A differs from that of the Sun by only 8 sec, with the result that the Taurus-A record is superimposed on a peak of a solar side lobe. In order to allow for the solar contribution on June 14 as well as on June 13 and 15, we determined the solar contribution by pointing the antenna two days later towards positions which the source had relative to the Sun on the occulting days of June 13, 14 and 15. This was done near the meridian transit as well as at other hour angles, in order to approximate the same antenna configurations as actually used. A good opportunity came on June 27, when the Sun had practically the same declination as on June 14, and the solar side lobe contribution was once again determined by simulating the occultation situation of June 14. Eliminating the solar contribution, we found, indeed, that the Taurus-A intensity significantly decreased on June 14.

It has been shown by several authors<sup>2,3,5,9</sup> that small-angle multiple scattering at electron density irregularities of the coronal streamers can account for the increase of angular size as well as the decrease of intensity of Taurus-A as its radiation passes within a small distance of the Sun. The observed decrease of intensity on 430 Mc/s and the small, but apparently significant, increase of angular size indicate that the same scattering mechanism may be applicable over the entire range of frequencies 26-430 Mc/s.

I thank Mr. H. E. Hardebeck for helping with the observations. This work was supported by the Advanced Research Projects Agency of the United States Department of Defense as part of project DEFENDER and technically monitored by the Air Force Office of Scientific Research.

## ASTROPHYSICS

### Soft X-ray Image of the Sun

ON August 11 a soft X-ray photograph of the Sun (Fig. 1) was obtained from a three-axis stabilized rocket vehicle. The head of a Skylark rocket launched from Woomera, Australia, was stabilized by a three-axis system developed by Elliott Bros., Space, and G.W. Division, under contract to the Royal Aircraft Establishment.

The firing was successful and during the exposure time of the pinhole camera the pointing noise was 3 arc.min peak to peak (p.t.p.), and 8 arc.min p.t.p., in the lateral planes and less than 5° p.t.p. in the roll axis. During the time of the exposure there was also a movement in the datum of one lateral axis of 6 arc.min.

The X-ray pinhole camera device consisted of nine pinholes, covering five wave-length ranges, mounted above an armoured film cassette. The cassette was provided with two spring-loaded shutters operated by solenoids to start and finish the X-ray exposure. The photograph reproduced was obtained from a camera of focal length 7.5 in. with a 0.005-in. pinhole. The filter used over the pinhole was of 1.5 $\mu$  plastic foil with a 1000-Å coating of aluminium. This filter passes soft X-rays in the region up to about 25 Å and also in the region 44-70 Å.

Fig. 1. Soft X-ray pinhole photograph of the Sun, 05:40 U.T., August 11, 1964. (The line running from the centre to the east limb is a scratch on the negative)

The photograph was obtained by exposure between 118 sec and 287 sec of the rocket flight, corresponding to 365,000 ft. on the upward journey to 362,000 ft. on the downward journey; peak altitude was 473,000 ft. The photographic medium was specially prepared by Mr. Hercock and his staff of the Products Research Laboratory, Ilford, Ltd., and had no supercoat covering the emulsion.

Comparison of this photograph with the Ca K plage photographs of Tokyo Observatory (Fig. 2) and the Fraunhofer Institut solar map (Fig. 3) shows a good correlation between the plage areas and the patches on the X-ray photograph. The X-ray emission defining the external edge of the disk of the photograph does not correlate with the plage areas and is thought to be due to coronal emission of soft X-rays and the limb brightening which would be expected due to the optically thin nature of the corona at these wave-lengths.

Comparison with the 9.1-cm spectroheliograph (Fig. 4) obtained by the Radio Astronomy Institute, Stanford, on August 10, 1964, 8 h before the X-ray photograph, shows generally good correlation of the bright patches and the limb areas.

Fig. 2. Ca K photograph of the Sun, 04:16 U.T., August 11, 1964. (By courtesy of Tokyo Observatory)

## PHYSICS

## Improved Test Cell Material for the Tetrahedral Anvil Apparatus

Test cells for ultra-high-pressure apparatus of the 'belt' or 'anvil' types<sup>1</sup> are typically made from pyrophyllite, a naturally occurring aluminium silicate. It is unlikely, however, that this material possesses an ideal combination of mechanical properties for this purpose, a view which is supported by the shape of the load/pressure calibration curve. Fig. 1 (curve A) shows this experimental relation for a 0.75-in. edge National Bureau of Standards type tetrahedral anvil apparatus using pyrophyllite tetrahedra. The usual resistance transitions in bismuth at 25.4 kbars (ref. 2), thallium at 36.7 kbars (ref. 2), and barium at 59 kbars (ref. 3) were used, with the specimen geometry shown. It will be noted that although at 25.4 kbars loads close to the nominal pressure (that is, load/anvil area) line B are obtained, at higher pressure there is a more or less linear fall-off towards high loads, the efficiency of pressure generation falling away rapidly. No explanation of this has as yet been published, but two likely hypotheses may be put forward: either (a) it is due to the load on the compressible gaskets, or (b) it is due to stress difference in the pyrophyllite (which can be high at high pressures)<sup>1</sup>, since the maximum principal stress would be expected to be normal to the anvil face in the pyrophyllite just below the surface. Experiments have been made with specially profiled and lubricated anvils<sup>4</sup>: these indicate that gasket loads are probably not significant throughout the pressure range, so that (b) is the more likely hypothesis. Since this involves a fundamental mechanical property, an alternative test cell material was sought with a different relation between shear strength and compressibility.

Two-phase materials were thought promising, and curve C of Fig. 1 shows the load/pressure relation for tetrahedra made from an epoxide resin filled with magnesia: 50–60 per cent by volume of 200-grade MgO was added to the resin ('Araldite' type MY740), and a liquid anhydride hardener. This was then cast into tetrahedral moulds and cured for 16 h at 120°C, plus 4 h at 150°C and 2 h at 200°C. A minimum of machining is required to produce finished tetrahedra, and the process is thus much simpler and cheaper than that using pyrophyllite. Curve C shows that the new tetrahedra are much more efficient at high pressures; further, that the load/pressure relation is now fairly close to the nominal load line, being displaced some 10–20 tons towards higher loads. It is interesting to note that the reverse transition loads observed for both pyrophyllite and the filled resin tetrahedra are very similar (curve D), and that the characteristics for the filled

Fig. 3. Solar map (by courtesy of the Fraunhofer Institut). Hatched areas indicate shredded and weak plagues; bordered areas represent continuous plagues

Fig. 4. 9.1-cm spectroheliograph, 20–21 h U.T., August 10, 1964. (By courtesy of the Stanford Radio Astronomy Institute)

The photograph was obtained at a period of quiet Sun and does not show the activity visible on the previous X-ray photographs<sup>1</sup>; it thus has the advantage of limited X-ray activity and limited Ca K plage activity for comparison. The overall lower activity and the greater sensitivity of the apparatus also reveals the limb brightening which was not apparent in the first photograph.

Further detailed analysis of the photograph is being undertaken, in particular in relation to X-ray flux measurements and detailed correlation.

I would like to thank, for most helpful discussions, all members of the Space Research Group at the University of Leicester, who are under the leadership of Prof. E. A. Stewardson, in particular Dr. K. A. Pounds, and also the workshop staff of the Department, who, under the direction of Mr. R. Cox, produced the camera. Mr. David Watson of the Department was responsible for the flight arrangements at Woomera.

Fig. 1. Load/pressure calibration curves. Inset, tetrahedron with face/face configuration. A, Pyrophyllite tetrahedra; B, nominal pressure line; C, filled epoxide tetrahedra; D, reverse transitions

Fig. 2. Resistance of bismuth specimen versus anvil load, for filled resin tetrahedron: transitions marked at 25.4 kbars, 26.9 kbars and 89 kbars

tetrahedra are now symmetrical about the nominal load line.

With the improved load/pressure characteristic, the 89 kbar bismuth transition<sup>5</sup> is easily accessible. Fig. 2 shows a typical variation of resistance of bismuth with pressure, and it may be noted in passing that we have not detected any discontinuity in slope which could be reconciled with the volumetric transitions reported by Bridgman at ~44 kbars and ~64 kbars (ref. 6). (The bismuth used in our experiments was 99.999 per cent pure.)

There is little doubt that pressures over 100 kbars can thus be attained without much difficulty in the tetrahedral apparatus; further, this new material should be of value in other types of gasketing ultra-high-pressure apparatus since its 'pressure equalizing properties' appear to be superior to those of pyrophyllite. Two possible disadvantages may be noted. First, at pressures  $\geq 75$  kbars violent explosions of the test cell have sometimes been encountered; these appear to be associated with too rapid a rate of loading. Secondly, experiments have not yet been performed at very high temperatures, and the filled resin may well turn out to be inferior to pyrophyllite in mechanical and electrical properties under such conditions.

We thank Miss A. Thake for carrying out many of the experiments, and the Plastics Department of Standard Telecommunication Laboratories, Ltd., in particular K. A. Pettican, for the special techniques used in producing the filled resins.

### Effect of Temperature on the Pre-breakdown Pulses of Conduction Current in Insulating Oils

It has been previously<sup>1,2</sup> reported that the pre-breakdown conduction current pulses in liquid dielectrics are very sensitive to test conditions and the composition of the test liquid. It has been found that a convenient way of investigating these pulses is to record them as a double

Fig. 1. Result of pulse height analysis. A, at 20° C; B, at 50° C

Fig. 2. Autocorrelation functions. A, at 20° C; B, at 50° C

trace on a high-speed magnetic tape (speed 75 in./sec). By using two play-back heads which can be displaced relative to each other it is possible to obtain the autocorrelation function of the random pulses. To reduce distortion and interference, frequency modulation before recording and demodulation during play-back were used.

The results here illustrate the statistical analysis and, as an example, show how the conduction current pulses are affected by a change in the temperature of the test liquid. This consisted of liquid paraffin, supplied by British Drug Houses, which was degassed at a pressure of  $10^{-3}$  mm mercury and filtered through a sintered glass filter of porosity No. 5 (average pore diameter  $1 \times 10^{-6}$  metre). Before the tests the sample was stress conditioned, that is, a stress of 450 kV/cm was applied for 2 h. Spherical nickel electrodes of 5 mm diameter with a gap spacing of  $125 \times 10^{-6}$  metre were used.

Fig. 1 shows the result of the pulse height analysis for an applied stress of 450 kV/cm. Curve A was obtained for a temperature of the liquid of 20° C and curve B for a temperature of 50° C. The corresponding autocorrelation functions for the two cases are given in Fig. 2. Using the method of Prony<sup>3</sup> for curve fitting, the following analytical expressions involving the sum of two exponentials were derived for the autocorrelation functions:

$$\text{Curve A } R(\tau) = 92.5e^{-912\tau} + 7.5e^{-4196\tau}$$

$$\text{Curve B } R(\tau) = 79.9e^{-1118\tau} + 20.1e^{-4187\tau}$$

The Fourier transform of these autocorrelation functions gives the power spectra according to the well-known Wiener-Khinchin relation. These spectra are shown in Fig. 3. For both the curve fitting and the computation of the power spectra a digital computer was used.

Fig. 3. Power spectra. A, at 20° C; B, at 50° C

It can be seen from Fig. 1 that the distribution of the pulse height is exponential, which seems to indicate that a multiplication process of the charge carriers takes place in the liquid. This figure also shows that increasing the temperature increases the current fluctuations. This is probably due to the resultant decrease in viscosity which in turn facilitates the motion of charge carriers in the bulk of the liquid. An inspection of the plots for the autocorrelation functions of Fig. 2 shows that no hidden periodicities are present in the random fluctuations. As can be seen from the power spectra of Fig. 3, the frequency-range of these fluctuations lies in the very low audio-frequency range. From Fig. 3 it is also clear that increasing the temperature results in an increase in the relative magnitude of the energy for all frequencies.

The experiments have shown that, as a rule, the effect of increasing the temperature or the applied stress is also to increase the relative magnitude (that is, the energy content) of the high-frequency components of the spectrum.

I thank Prof. M. W. Humphrey Davies for providing the facilities to carry out this work, and Dr. H. Tropper for his advice.

### Electrostatic Switching of One-dimensional Superconductors

LITTLE<sup>1</sup> has speculated on the possibility of synthesizing an organic superconductor; for an example he considers a macromolecule consisting of an axial long-chain 'spine' of alternately doubly and singly bound carbon atoms with a complex resonating aromatic dye type of side-chain attached to every alternate carbon atom. He argues that it is possible for the virtual oscillation of charge in this type of side-chain to provide a sufficiently attractive interaction with electrons moving in the spine for superconductivity to result. He suggests that since this is essentially an electronic oscillation coupling rather than a phonon-coupled interaction, a very high transition temperature may result and room-temperature superconductivity may be possible; the biological implications of this are, of course, of great significance.

Ferrell<sup>2</sup> has since questioned these predictions on the grounds that the macromolecule is essentially a one-dimensional superconductor and that restricting the BCS Hamiltonian for the interaction to one dimension must introduce compressional modes of vibration to satisfy the requirements of gauge invariance. He suggests that these modes may dominate in one dimension and prevent the establishment of the long-range order required for superconductivity. The effect of these compressional modes will be determined by the side-chain structure and the interactions between an electron travelling along the macromolecule's spine and sites in the side-chain. Little has chosen a well-screened side-chain in order to reduce these interactions. It is to be hoped that a suitable side-chain, which will allow room-temperature superconductivity, can be found.

The type of macromolecule required is essentially a long-chain organic polymer. Little considers that this might be cross-coupled to produce a web-like structure; however, it appears that preferential orientation of the molecules along the macromolecule axis would be relatively simple to synthesize by the 'nylon' spinning technique, and if coupling between molecules can then be arranged—and this is quite feasible for some organic polymers—a long thread of superconductor could be produced. The ends of a thread might also be cross-linked to form a loop.

The superconducting thread would display a strong anisotropy; it would be superconducting along its length, corresponding to the molecular axis, but normal to this direction the types of organic molecules envisaged would probably be good electrical insulators. Magnetic field effects would be very different along and normal to the molecular axis, but it is of even greater significance that it would be possible to maintain an electric field in the superconductor.

The effect of an electric field applied across a superconducting thread will be to distort the screening effects of the side-chain and to modify the wave functions of the side-chain given by Little; the side-chain interaction will be altered and superconductivity will eventually be destroyed.

There is, therefore, the possibility of electrostatically switching a one-dimensional superconductor into its normal resistive state as well as the customary magnetic switching effects.

The matrix elements of the interactions considered by Little are in the range of 1 eV. The order of magnitude of perturbing voltage required to destroy these interactions and produce switching will probably be a small percentage of a matrix element of interaction, perhaps 10 mV. The chain diameter of the macromolecule considered by Little is 30 Å, so that the critical electric field would be of the order of 33,000 V/cm—this could be very convenient for electronic switching applications; much more so than magnetic switching in all probability, since this would probably require extremely high magnetic fields.

An even more interesting speculation is that the sort of switching voltages required, if small superconducting memory loops of this type exist in the brain, would be quite consistent with the sorts of voltage signals known to exist in the nervous system. The type of organic macromolecular superconductor Little has suggested might provide a memory system for the brain, and interrogation or storage could be performed by electrostatic switching with voltages compatible with the nervous system. Further speculation suggests, by comparison with associative cryoelectric computer memories, that interrogation could be non-destructive.

# Recoil Effects of Neutron Reactions in Sodium Bromate

THE chemical effects following radioactive neutron capture and isomeric transition of the nuclei of bromine atoms in bromates have been studied by a number of investigators<sup>1</sup>. The present communication describes our investigation of the chemical distribution of radioactive bromine atoms arising from  $^{79}\text{Br}(n,2n)^{78}\text{Br}$  and  $^{79}\text{Br}(n,\gamma)^{80}\text{Br}$  reactions in crystalline sodium bromate. The effects of the irradiation and dissolution temperatures were investigated and the recoil effects of both nuclear reactions were compared.

Powdered sodium bromate was irradiated with fast neutrons produced by the  $^3\text{H}(d,n)^4\text{He}$  reaction, or with slow neutrons moderated in paraffin blocks. The irradiated salt was dissolved in water and the bromine species of lower oxidation states were separated from bromate by extraction with carbon tetrachloride containing a small amount of molecular bromine, or by precipitation of bromide as silver bromide. The radioactivity of  $^{78}\text{Br}$  (half-life, 6.4 min) or  $^{80}\text{Br}$  (half-life, 18 min) was measured by means of a Geiger-Müller counter or an NaI scintillation counter.

The results are summarized in Table 1. The mean values of repeated determinations are shown together with the standard deviations.

Table 1. THE RETENTION OF RADIOBROMINE ATOMS FOLLOWING  $(n,2n)$  AND  $(n,\gamma)$  REACTIONS IN SODIUM BROMATE

Temperature Irradiation	Room temperature Dissolution	$^{79}\text{Br}(n,2n)^{78}\text{Br}$ Solvent extraction (per cent)	$^{79}\text{Br}(n,2n)^{78}\text{Br}$ Precipitation (per cent)	$^{79}\text{Br}(n,\gamma)^{80}\text{Br}$ Solvent extraction (per cent)	$^{79}\text{Br}(n,\gamma)^{80}\text{Br}$ Precipitation (per cent)
Room temperature	Room temperature	$12.4 \pm 0.4$	$11.5 \pm 0.4$	$12 \pm 1$	$11 \pm 1$

\* Dissolved in a eutectic mixture of lithium chloride and water.

The retention values of  $^{80m}\text{Br}$  and  $^{82}\text{Br}$  in slow neutron irradiation of solid sodium bromate have been reported by several authors<sup>2-6</sup>. The results range from 4 to 25 per cent depending on the conditions of irradiation and separation. Jach and Harbottle reported that, when alkali bromate was irradiated at dry-ice temperature, nearly the same retention values were obtained for  $^{80m}\text{Br}$  and  $^{82}\text{Br}$  recoil atoms from  $(n,\gamma)$  reactions, whereas an isotopic effect appeared as the irradiated salts were annealed at  $200^\circ\text{C}$ . Our results for  $^{80}\text{Br}$  are in good agreement with the initial retention values for  $^{80m}\text{Br}$  and  $^{82}\text{Br}$  obtained by them.

Although it is generally observed that the retention is sensitive to irradiation and dissolution temperatures, our attempts at low-temperature irradiation and dissolution resulted in no marked decrease of the retention values. This confirms the results reported by previous workers in the case of  $^{80m}\text{Br}$  and  $^{82}\text{Br}$  recoil atoms from  $(n,\gamma)$  reactions in potassium bromate<sup>7</sup>.

Comparison of recoil effects in  $(n,\gamma)$  and  $(n,2n)$  reactions has been attempted by several investigators. In all alkyl iodides that have ever been investigated almost the same retention values have been reported for both reactions<sup>8,9</sup>. On the other hand, different retention values have been observed in propyl bromides<sup>10</sup>, molecular iodine dissolved in various hydrocarbons<sup>11</sup>, and cobalt complexes<sup>12</sup>. In sodium bromoacetate, the retention of  $^{80m}\text{Br}$  atoms in  $(n,2n)$  reaction has been found to be very similar to that of  $^{82}\text{Br}$  atoms in  $(n,\gamma)$  reaction, whereas  $^{80m}\text{Br}$  atoms arising from  $(n,\gamma)$  reaction have showed somewhat different retention values<sup>13</sup>. Larger recoil energy involved in the  $(n,2n)$  reactions and the annealing effect of recoil protons have been suggested as the possible cause of such differences.

The data presented in this communication indicate that in sodium bromate there exists no difference, within experi-

mental errors, between the retentions for both reactions. Although no theoretical or experimental estimate of the recoil energy of  $(n,2n)$  reactions is as yet available, it would be reasonable to presume that the incident fast neutron or the outgoing two neutrons impart far larger recoil energy to the atom than the capture  $\gamma$ -quanta emitted in  $(n,\gamma)$  reactions. It is noteworthy in an experimental estimate of recoil mechanism that in certain compounds, such as alkyl iodides and sodium bromate, the retention seems to remain unaffected by a large change in recoil energy.

Further work is in progress on other bromates.

## GEOPHYSICS

### Depth of the Mohorovičić-discontinuity under the North Sea Basin

DURING this summer and autumn refraction seismic experiments were carried out on the North Sea on a line with azimuth  $150^\circ$  starting from a position  $54^\circ 40' \text{N}$  and  $3^\circ 20' \text{E}$ . The so-called velocity-depth method was adopted in which listening ship and shooting ship are in mirror position with regard to the starting point. In this way the effect of a possible tilt of the layers is eliminated. This has the advantage that no need exists for shooting a reversed profile.

The preliminary results are listed in Table 1.

Velocity	Thickness	Depth
1,500 m/sec	40 m	40 m
1.85 km/sec	2.2 km	2.2 km
3.0 km/sec	1.0 km	3.2 km
6.15 km/sec	26.5 km	30 km
8.3 km/sec		

Velocity-depth profile at  $54^\circ 40' \text{N}$ ,  $3^\circ 20' \text{E}$ .

The Conrad-discontinuity did not show up in the first arrivals. The heaviest charge was somewhat less than 3,000 kg TNT at a distance between the ships of 210 km. In all, 46 shots were made. More than half of them had a purely experimental character. In fact, quite a few charges were fired to find the appropriate charge-distance relation for this region. The experiments were carried out on ships of the Royal Netherlands Navy. On all the trials H.Neth.M.S. *Cerberus* acted as the shooting ship. The explosives used were surplus depth charges.

The measurements form part of a larger programme to investigate the relation between sedimentary thickness and the position of the Moho. This first result seems to

confirm the conclusion<sup>1</sup> drawn from gravity data, that in general the mass deficiency of the North Sea Basin sediments is compensated isostatically.

## GEOLOGY

### Bauchite: a New Variety in the Quartz Monzonitic Series

THE name 'bauchite' is proposed for a coarse plutonic fayalite-bearing rock which was first described by me from Bauchi in northern Nigeria<sup>1</sup>. I share the reluctance of modern petrologists to propose new variety names for rocks. There are, however, cases in which a variety name is justifiable to imply a significant physical, chemical or petrological characteristic not adequately conveyed by the general or group name. The case of charnockite is an example: to have simply described a charnockite as a hypersthene granite would never have conveyed the petrological peculiarities of the rock.

Variety names may therefore be justified if the rock to be named satisfies the following conditions: (1) the rock has a fairly large occurrence covering a few square miles, or in the case of dykes if they are found widespread over a few square miles; (2) it is found in two or more localities in similar petrological settings; (3) it possesses certain invariable physical, mineralogical or chemical characteristics by which it is distinguished from other rocks; (4) these invariable characteristics are the result of unusual petrogenetic history of the rock and are found in all specimens from different localities without exception.

When the fayalite quartz monzonitic rock of the Nigerian basement complex was considered in the light of these criteria, it was found necessary to propose a special name for it. This rock, which has been fully described by me<sup>1</sup>, is usually very coarse grained with the microcline perthite averaging 3 cm by 2 cm. It is of peculiar dark brownish-green colour—much too dark for its mineralogical composition. This colour is invariable, and is its most distinguishing physical characteristic. In general appearance, it bears resemblance to larvikite, but it is composed of perthite, plagioclase, fayalite, pyroxene, amphibole, quartz and ore. Myrmekitic intergrowths of plagioclase and quartz are widespread around the margins of the perthite. In view of the extreme coarseness of the rock, conventional methods of modal analysis were found useless. Using enlarged photographs of large stained hand specimens<sup>2</sup>, the variation in the perthite:plagioclase:quartz ratios suggests that the rock, belonging to the quartz monzonitic series, varies from the quartz syenite to adamellite.

The rock is mineralogically distinguished by the presence of fayalite commonly associated with ferrohastingsite, with the latter invariably developed as a mould round the plagioclase and the fayalite developed inside the quartz grains. Chemically, the rock is characterized by high FeO and very low MgO.

The rock is now known to be fairly widespread in Nigeria. Around Bauchi town a single occurrence covers about 20 square miles. Other bodies, each as large as this, occur to the south and west of Bauchi. Large outcrops of the rock have recently been found in three other widely scattered localities in northern and western Nigeria.

In all these localities the rock is found to occur surrounded by coarse granite of very similar texture with

a gradational contact relationship, marked in the field only by a sudden change of colour from the light colour of the granite to the dark green colour of the bauchite. Petrographic investigation reveals that the rock often shows a fringing zone of charnockite towards its contact with the granite, as hypersthene takes the place of fayalite around the contact areas. This relationship as well as the greenish colour common to both suggest some petrogenetic affinity between charnockite and bauchite. The latter cannot, however, be described as charnockite as hypersthene is not generally found with the fayalite in this rock.

1, ME 101, fayalite quartz-monzonite, Kobi Hill, Bauchi.

2, ME 222, fayalite quartz-monzonite, Kofar Wombai Hill, Bauchi. Both analyses by the Colonial Geological Surveys (Mineral Resources Division), London.

Norm calculations made by me, after Barth (1951, pp. 79-81).

I have been engaged in the investigation of the rock, and from a consideration of the structural and petrological characteristics of the rock have concluded that the bauchite originated by an emanation into granite of ferrous iron rich fluid or magma<sup>3</sup>. The green colour of charnockite and bauchite is believed to be due to impregnation of feldspars with ferrous iron during the emanation. Fayalite was crystallized as a result of reaction between quartz and the emanation; and ferrohastingsite by reaction with plagioclase feldspars. The physical factors that determine whether fayalite or hypersthene will crystallize are not clear to me, but in view of the relationship of charnockite as fringe to bauchite, it may very well be temperature.

The occurrence of high-level intrusive fayalite-bearing granitic rock in the younger granite province of Nigeria<sup>4</sup> may be of some significance. Here, the fayalite-bearing rocks occur as ring or polygonal dykes associated with most of the ring-complexes of this province and vary from syenite to granite porphyry. These rocks are also invariably green but usually of lighter shade. The exact relationship of these to the rock in this account is not yet clear.

In conclusion, the name bauchite is used to denote a dark greenish fayalite-bearing rock of quartz syenite to adamellite mineralogical composition which was first described from Bauchi town in northern Nigeria<sup>1</sup>. Its salient and diagnostic characteristics are: (1) The feldspar of the rock, a micropertthite, is dark green in colour and the quartz is brownish-green with resinous lustre. (2) Fayalite occurs in association with amphibole and is commonly arranged in zones. The amphibole is commonly moulded around the plagioclase and the fayalite is usually in a quartz matrix. (3) The rock occurs in plutonic setting commonly fringed by charnockite and surrounded by a plutonic granite.

## METALLURGY

## Influence of Impurities on the Oxidation of Fe-26Cr Alloys

Most research on the oxidation of alloys has been done using commercial materials. In recent years, however, there has been a great deal of effort to work with pure alloys in order to obtain a better understanding of the mechanism of oxidation of these materials<sup>1</sup>. This laboratory has been investigating the oxidation of Fe-26Cr alloys and comparing the results with those obtained using stainless steels. This communication describes the high-temperature oxidation behaviour of three vacuum-melted alloys and one commercial steel. The compositions of the materials are given in Table 1.

Table 1

	C	Mn	Si	Ni	Cr
Fe-Cr	0.022	0.003	0.02	0.02	26.2
Fe-Cr-Si	0.022	0.004	0.55	0.02	26.2
Fe-Cr-Mn	0.012	1.00	0.01	0.02	25.7
Type 446	0.18	0.75	0.86	0.32	25.9

The specimens were first mechanically polished to produce a flat surface, and electro-polished in perchloric-acetic acid to remove surface contamination. They were then annealed at 1,100° C in argon, re-electropolished, and finally etched to remove the film left after electropolishing. Oxidation was carried out in a stream of dry oxygen. Continuous weighings were made on an automatic balance.

Typical weight-gain/time curves at 1,090° C are shown in Fig. 1. It can be seen that the Fe-26Cr and Fe-26Cr-0.5Si pure alloys oxidize at a similar rate and appreciably more slowly than the commercial alloy and the pure alloy containing manganese.

Fig. 1. Oxidation of Fe-26Cr, Fe-26Cr-0.5Si, Fe-26Cr-1 Mn and type 446 in 1 atm. dry oxygen at 1,090° C

After these oxidation runs the samples were examined metallographically and the scales analysed by X-ray diffraction and spectrographic analysis. Typical cross-sections of the oxidized specimens are shown in Fig. 2. The only oxide phase formed on the binary Fe-Cr alloy was  $\alpha$ - $\text{Cr}_2\text{O}_3$  containing a small amount of iron. (Pure chromium formed a similar single-phase scale under comparable conditions<sup>2</sup>.) The scales formed on the other three alloys are quite different. In the Fe-Cr-Si ternary, the silicon oxidizes preferentially to form a silica sub-scale under a layer of ' $\text{Cr}_2\text{O}_3$ ' indistinguishable from the oxide on the Fe-Cr binary. The reason the oxidation rate is not affected is because a continuous layer of silica does not form. The protectiveness of the ' $\text{Cr}_2\text{O}_3$ ' layer remains unchanged. In the Fe-Cr-Mn ternary, the Mn also oxidizes preferentially but forms an Mn-Cr spinel as a continuous layer at the expense of some of the ' $\text{Cr}_2\text{O}_3$ '. No scale section of the commercial steel is shown but, because of its manganese content, it forms a similar scale of spinel

Fig. 2. Metallographic sections through oxide layers formed at 1,090° C. Wrinkled oxide and rugged metal surface are caused by compressive stress that develops continuously in the thickening oxide. R, rhombohedral  $(\text{Cr,Fe})_2\text{O}_3$ ; S,  $\text{MnO.Cr}_2\text{O}_3$  spinel; X, cristobalite silica. (a) Fe-26Cr alloy (curve 1).  $(\text{Cr,Fe})_2\text{O}_3$  is only phase formed. ( $\times$  c. 375). (b) Fe-26Cr-0.5Si (curve 2). Islands of silica have formed below  $(\text{Cr,Fe})_2\text{O}_3$  layer. ( $\times$  c. 750). (c) Fe-26Cr-1 Mn (curve 3). Light grey oxide is  $(\text{Cr,Fe})_2\text{O}_3$ ; darker grey is  $\text{MnO.Cr}_2\text{O}_3$  spinel ( $\times$  c. 750).

and ' $\text{Cr}_2\text{O}_3$ ' layers. Silica occurs again as a sub-scale. The high oxidation rate of the two alloys containing manganese is the result of the presence of the  $\text{MnO.Cr}_2\text{O}_3$  spinel.

These results indicate that manganese is a deleterious additive to FeCr alloys from the point of view of high-temperature oxidation. The addition of 0.5 per cent silicon does not improve oxidation resistance. It would appear that the investigation of the pure alloys is not only useful for elucidation of the oxidation mechanisms but may also lead to the development of materials with higher oxidation resistance. This investigation indicates that the pure binary alloy is the most oxidation resistant. Further work is in progress.

## CHEMISTRY

## Hydrolysis of Ferrous Ions: a Kinetic Method for the Determination of the Fe(II) Species

WE have recently shown<sup>1</sup> that the increase in the rate of the reaction of Fe(II) with hydrogen peroxide obtained by the addition of anions,  $\text{X}^{n-}$ , such as  $\text{Cl}^-$ ,  $\text{SO}_4^{2-}$ ,  $\text{P}_3\text{O}_9^{3-}$  and  $\text{HP}_3\text{O}_9^{2-}$ , is due to the species  $\text{FeX}^{2-n}$  reacting more rapidly with hydrogen peroxide than the hexa-aquo-ferrous ion. Following Hardwick's single observation<sup>2</sup> in perchlorate media that the rate at  $[\text{H}^+] = 5.3 \times 10^{-4}$  M is slightly greater than at lower pH, we have extended our investigation to higher pHs. We find that the observed bimolecular rate constant  $k_0$  in perchlorate media under nitrogen remains constant over a wide range of acidity, and then changes quickly over a narrow pH range to a higher limiting value which remains unchanged when the acidity is decreased further. Such a plot of  $k_0$

Fig. 1. Plot of  $k_0$  against hydrogen ion activity at  $\mu = 1.0$  and  $25^\circ \text{C}$ 

against  $[\text{H}_3\text{O}^+]$  is shown in Fig. 1, and resembles curves usually associated with acid-base reactions, for example, a titration curve.

The possibility that this curve is caused by the influence of the dissociation:

can be ruled out:  $K$  calculated at ionic strength  $\mu = 1.0$  and  $25^\circ \text{C}$  from the available data<sup>3</sup> equals  $5.4 \times 10^{-12}$  moles litre<sup>-1</sup>, and this dissociation obviously occurs at a higher  $p\text{H}$  than the rapid rise in  $k_0$  in Fig. 1. However, comparison with the effects of other anions<sup>1</sup> suggests that this curve is due to the conversion of the hexa-aquoferrous ion into a species with a positive charge  $< 2$ , which then reacts more rapidly with hydrogen peroxide. The constancy of  $k_0$  at high  $p\text{H}$  suggests that only one such species exists, probably  $\text{FeOH}^+$ , with the mechanism:

where  $\text{Fe}^{2+} + \text{H}_2\text{O}$  and  $\text{FeOH}^+$  have their co-ordination spheres completed with water molecules and

$$K_h = [\text{FeOH}^+][\text{H}_3\text{O}^+]/[\text{Fe}^{2+} + \text{H}_2\text{O}]$$

The lower limiting value of  $k_0$  is equated with  $k_1$ , and the higher limiting value with  $k_h$ . The rate of formation of ferric ions would be given by:

$$\begin{aligned} \frac{d[\text{Fe(III)}]}{dt} &= 2k_0[\text{Fe(II)}][\text{H}_2\text{O}_2] \\ &= 2k_1[\text{Fe}^{2+} + \text{H}_2\text{O}][\text{H}_2\text{O}_2] + 2k_h[\text{FeOH}^+][\text{H}_2\text{O}_2] \end{aligned}$$

where  $[\text{Fe(II)}]$  is the total concentration of ferrous ions in solution. It can be shown that:

$$k_0 = \frac{k_1[\text{H}_3\text{O}^+] + k_h K_h}{[\text{H}_3\text{O}^+] + K_h}$$

and for the condition that  $[\text{H}_3\text{O}^+] = K_h$ ,  $k_0 = (k_1 + k_h)/2$ . Therefore,  $K_h$  can be found from Fig. 1, being equal to  $[\text{H}_3\text{O}^+]$  where  $k_0 = (k_1 + k_h)/2 = 290$  l.moles<sup>-1</sup> sec<sup>-1</sup>. At this value of  $k_0$  the hydrogen ion activity  $\alpha_{\text{H}^+} = 3.2 \times 10^{-4}$ ; an approximate value for the activity coefficient of perchloric acid  $f_{\pm}$  in dilute solutions in 1 M  $\text{NaClO}_4$  can be computed<sup>4</sup> from the geometric mean of the activity coefficients of 1 M  $\text{HClO}_4$  and 1 M  $\text{NaClO}_4$ , the latter values being interpolated from the available experimental data<sup>5,6</sup>. In this way at  $\mu = 1.0$  and  $25^\circ \text{C}$   $K_h = \alpha_{\text{H}^+}/f_{\pm} = 4.3 \times 10^{-4}$  moles litre<sup>-1</sup>. As expected for such an ion-neutral

molecule reaction<sup>1</sup>,  $k_h$  is independent of ionic strength:  $K_h$  is found to vary slightly with  $\mu$ .

$K_h$  has been determined by several workers by measurement of  $[\text{H}_3\text{O}^+]$  produced by ferrous ion in conductivity water or water approaching neutral point. These values are collected in Table 1 and vary widely among themselves. Some are measured in the presence of a precipitate of ferrous hydroxide, and some use ferrous chloride solutions where ferrous is known to complex<sup>1</sup>: the last two measurements quoted in Table 1 are virtually by the same experimental procedure and yet the results differ considerably. The value found kinetically in this present work is very much greater than any of those of the previous workers derived by  $p\text{H}$ -difference. The kinetic method differs from the other methods in two respects: the quantities determined are really  $[\text{Fe}^{2+} + \text{H}_2\text{O}]$  and  $[\text{FeOH}^+]$  (cf. the other anions<sup>1</sup>) and not  $[\text{H}_3\text{O}^+]$  as in the other determinations; the hydrolysis is controlled by the addition of acid to the system. We have re-determined  $K_h$  by  $p\text{H}$ -difference (a) with ferrous perchlorate in conditions of added acid (b) in the same way as the previous workers by dissolving ferrous perchlorate in conductivity water. In all the calculations the observed hydrogen ion activities were converted to  $[\text{H}_3\text{O}^+]$  using the approximate value for activity coefficient at  $\mu = 1.0$  as described in the kinetic measurements here. Table 2 shows that (a) produces a value of  $K_h$  independent of total added ferrous ion concentration, and the average value of  $K_h = 4.8 \times 10^{-4}$  is in excellent agreement with that produced here by the kinetic method under the same conditions. The value of  $K_h$  by (b) varies with  $[\text{Fe(II)}]$  and is of the same order as that found by previous workers under their conditions. The concentration of ferric ions in these solutions was found to be negligible using the thiocyanate method.  $p\text{H}$  was measured using a glass electrode and the expanded scale of a Pye Dynacap direct-reading instrument. These results indicate that the hydrolysis appears to be inhibited at the higher  $p\text{H}$ : here the ratio  $[\text{H}_3\text{O}^+]$  produced/ $[\text{Fe(II)}]$  at equilibrium is much lower than at the lower  $p\text{H}$ . This suggests that, at the higher  $p\text{H}$ , a hydrolysed species (probably not  $\text{FeOH}^+$ ) removes hexa-aquoferrous ions into a less hydrolysable form, possibly a polymer of a basic cation type: this may account for the turbidity which is always produced under these conditions.

Under the controlled conditions with added acid used by us, the agreement between the two methods, kinetic and  $p\text{H}$ -difference, together with the constancy of  $k_0$  at

$1.00 \times 10^{-1}$	$1.1 \times 10^{-7}$

high  $pH$ , suggest that only one equilibrium, equation (1), exists here. However, the average value of  $K_h$ ,  $4.6 \times 10^{-4}$  moles litre $^{-1}$ , is much higher than the values of  $K_h$  recorded for some other bi-positive cations of the first transition series<sup>12</sup>. Although the crystal field stabilization for the hexa-aquo cation  $M^{2+}$  over that for  $MOH^+$  is probably less for  $Fe(II)$  than the other cations in the series except  $Mn(II)$ , this difference is not likely to be great enough to account for the large value of  $K_h$  for  $Fe(II)$ . However, these values of  $K_h$  for the other cations have been determined by experiments involving the measurement of  $pH$ -difference in a similar manner to that used by the previous workers for ferrous ions<sup>7-11</sup>.

$K_c$  for the ion association:

is found to be  $2.0 \times 10^{10}$  using  $K_w = 1.007 \times 10^{-14}$  at  $25^\circ C$  and  $f_{H^+} f_{OH^-} / a_{H_2O} = 0.537$  at  $\mu = 1.0$  and  $25^\circ C$  as found for solutions containing  $NaCl$  (ref. 13). This is approximately  $10^8$  times bigger than the association constants<sup>1</sup> of  $Fe^{2+}$  with  $Cl^-$ ,  $SO_4^{2-}$ ,  $P_3O_9^{3-}$  and  $HP_3O_9^{2-}$ . A hydrolytic species, such as  $FeOH^+$ , is most certainly an inner sphere complex<sup>14</sup> and the others may therefore possibly be of the outer sphere type: alternatively, the high  $K_c$  for  $FeOH^+$  may be due to a high covalent contribution in the bonding.

## Hydrolysis of the Manganic Ion

RECENTLY the kinetics of the reactions of manganic perchlorate in aqueous solution have become the subject of investigation, but so far the species of  $Mn(III)$  present have not been identified. From a spectrophotometric investigation of manganic perchlorate solutions prepared electrolytically, we find maxima in the region of 203–220  $m\mu$  and at 470  $m\mu$  and a minimum of 350  $m\mu$ . The results of a detailed examination of such solutions at  $25^\circ C$  in the region 300–550  $m\mu$  with acidity varying between 0.10 M and 3.70 M  $HClO_4$  at an ionic strength  $\mu = 4.0$  maintained by the addition of manganous perchlorate (which also stabilizes the manganic ion) can be interpreted in terms of only one equilibrium:

where  $Mn^{3+} + H_2O$  is the hexa-aquo ion and  $MnOH^{2+}$  the hydroxopenta-aquo ion having extinction coefficients  $\epsilon_1$

and  $\epsilon_2$ , respectively. The observed extinction coefficient  $\epsilon$  should follow:

$$\epsilon([H_3O^+] + K) = \epsilon_1[H_3O^+] + \epsilon_2K \quad (1)$$

and rearranging:

$$\left(1 - \frac{\epsilon_1}{\epsilon}\right)[H_3O^+] = \frac{K\epsilon_2}{\epsilon} - K \quad (2)$$

When  $\epsilon_1/\epsilon$  is sufficiently  $< 1$ , a plot of  $[H_3O^+]$  against  $1/\epsilon$  at a fixed wave-length should be approximately linear. Such plots are found to be linear up to about 1.0–1.5 N  $HClO_4$ ; examples are shown in Fig. 1. From this plot at each wave-length an approximate value for  $K$  is found from the intercept, and then from the slope an approximate value for  $\epsilon_2$ ; by substitution of these values back in equation (1) an approximate value for  $\epsilon_1$  is obtained. This is then used in the full equation (2), and  $(1 - \epsilon_1/\epsilon) \times [H_3O^+]$  plotted against  $1/\epsilon$  for each wave-length for the whole acidity range 0.10–3.70 N  $HClO_4$ : fine adjustment is made to  $\epsilon_1$  to give the best straight line in each case over the whole acidity range, thus giving an accurate value for  $\epsilon_1$ , and accurate values for  $K$  and  $\epsilon_2$  from the intercept and slope respectively.

Fig. 1. Plots of  $[H_3O^+]$  against  $1/\epsilon$  for various wave-lengths at  $\mu = 4.0$  and  $25^\circ C$

The spectra for the hexa-aquo ion and the hydroxopenta-aquo ion both have a maximum of 470  $m\mu$  and a minimum of 350  $m\mu$ :  $\epsilon_1 = 52$  and  $\epsilon_2 = 165$  at 470  $m\mu$  and  $\epsilon_1 = 0.50$  and  $\epsilon_2 = 28$  at 350  $m\mu$ :  $\epsilon_1$  and  $\epsilon_2$  both have a maximum in the region 203–225  $m\mu$  with  $\epsilon \sim \epsilon_1 \sim \epsilon_2 \sim 4 \times 10^3$ , but the exact wave-length of the maximum is dependent on conditions. From the analysis of the results at fifteen wave-lengths over the range 300–550  $m\mu$ ,  $K = 0.88 \pm 0.04$  at  $\mu = 4.0$  and  $25^\circ C$ . From similar analyses at 300  $m\mu$  and 470  $m\mu$  over the temperature range  $1^\circ$ – $35^\circ C$  it was found for  $\mu = 4.0$  that  $\Delta H = 4.8 \pm 0.8$  kcal mole $^{-1}$  and  $\Delta S = 15.7 \pm 2.6$  cal deg $^{-1}$  mole $^{-1}$ , with  $\Delta G$  at  $25^\circ C = 123$  cal mole $^{-1}$ . Solutions were used immediately after preparation and the total  $[Mn(III)]$  was determined by oxidizing  $Fe(II)$  to  $Fe(III)$  in perchlorate media,  $[Fe(III)]$  being estimated spectrophotometrically at 260  $m\mu$ . No interference from polymers of  $Mn(III)$  could be detected: Beer's law is obeyed by the solutions of manganic perchlorate at both the low and the high end of the acidity range. While this work was in progress approximate values for  $K$  were published: Diebler and Sutin<sup>1</sup> give  $K \sim 5$  and Fackler and Chawla<sup>2</sup> give  $K \sim 1.5$ , both at  $\mu = 6.0$  and  $23^\circ C$ . Although Diebler and Sutin used aged solutions of  $Mn(III)$  which contain polymers, these approximate values support the conclusion from the accurate value by

us that the hexa-aquamanganic ion is considerably hydrolysed even in a very high concentration of acid. This value of  $K$  is high compared with those for the other tripositive ions of the first transition series (following communication). The crystal field stabilization of the hexa-aquo ion over the hydroxopenta-aquo species will be smaller for Fe(III) than Mn(III), so this effect alone cannot control the hydrolysis as  $K$  for Mn(III)  $\gg$  Fe(III) ( $K = 10^{-3}$  at  $\mu = 3$  and  $25^\circ\text{C}$  (ref. 3)).

One of us (G. D.) thanks the Department of Scientific and Industrial Research for the award of a maintenance grant.

### Hydrolysis of the Tripositive Ions of the First Transition Series: a Discussion of the Heats and Entropies for the Dissociation of the First Proton

THERMODYNAMIC data are now available for the reaction

for all members of the first transition series which form a reasonably stable hexa-aquo ion  $M^{3+}$  in solution except titanous. These are collected in Table 1 for perchlorate media, where possible at ionic strength  $\mu = 1.0$ : the equilibrium constant  $K = [MOH^{2+}][H_3O^+]/[M^{3+}]$  at  $25^\circ\text{C}$  is also included, the value for titanous at  $\mu = 1.0$  being interpolated from the data of Pecsok and Fletcher<sup>6</sup>. As the first hydrolysis product  $MOH^{2+}$  must be an inner sphere complex<sup>7</sup>, changes in  $\Delta H$  for reaction (1) along the first transition series might be expected to arise from changes in the difference between the crystal field stabilizations produced by  $H_2O$  and  $OH^-$ . The crystal field splitting is greater for  $H_2O$  than  $OH^-$  and in general should result in stabilization of the hexa-aquo ion: this stabilization is absent for the  $t_{2g}^3e_g^2$  arrangement, and therefore  $K$  for the tripositive ions in the first transition series should have a maximum at ferric ion. However, Table 1 shows clearly that this is not the case, indicating that the influence of differences in crystal field stabilization on reaction (1) must be small. In fact, the spectral data<sup>8</sup> for the rhodium(III) complexes  $Rh(NH_3)_5H_2O^{3+}$  and  $Rh(NH_3)_5OH^{2+}$ , where the wave-lengths of maximum absorption are  $31,600\text{ cm}^{-1}$  and  $31,200\text{ cm}^{-1}$ , respectively, suggest that the difference in stabilization produced by  $H_2O$  and  $OH^-$  will be small enough to neglect when considering changing influences on reaction (1) along a transition series.

Mn<sup>3+</sup> has the largest value for  $K$  at  $25^\circ\text{C}$ , and the next largest values are for Co<sup>3+</sup> and Ti<sup>3+</sup>. V<sup>3+</sup> and Fe<sup>3+</sup> are hydrolysed to the same extent and have nearly

identical values for  $\Delta H$  and  $\Delta S$ . Cr<sup>3+</sup> is much less hydrolysed than V<sup>3+</sup> and Fe<sup>3+</sup>, and this is due to a smaller entropy change as  $\Delta H \sim 10\text{ kcal mole}^{-1}$  for all three ions. The high value of  $K$  for Mn<sup>3+</sup> is due to the value for  $\Delta H$  being less than those for V<sup>3+</sup> and Fe<sup>3+</sup>. For Co<sup>3+</sup>  $\Delta H \sim 10\text{ kcal mole}^{-1}$ , and the value of  $\Delta S > 20\text{ e.u.}$  is responsible for  $K$  being higher than the value for V<sup>3+</sup> or Fe<sup>3+</sup>. As Co<sup>3+</sup> is the only ion in Table 1 which is supposed to be in a low spin state this will be considered separately later.

The entropy change is always positive in going from left to right in reaction (1), indicating a general decrease in restriction: this is probably due to the partial neutralization of the overall change in the hydroxopenta-aquo ion from the adjacent  $OH^-$  with a consequent decrease in restriction imposed on the solvent molecules, even though the number of species bearing a positive charge has increased. However, changes in this positive  $\Delta S$  for reaction (1) along a transition series might be expected to be related to changes in the metal-ligand distances within the hydrated cations themselves. As the ion-ion attraction of  $M^{3+}$  for  $OH^-$  will be greater than the ion-dipole attraction of  $M^{3+}$  for  $H_2O$ , the metal-ligand distance for  $OH^-$  should be shorter than for  $H_2O$ , causing the hydroxopenta-aquo ion itself to have a lower entropy than the hexa-aquo ion: any screening of this attraction should therefore have a proportionately greater effect on the ion-ion interaction of the  $OH^-$  tending to increase the positive entropy change  $\Delta S$ . Therefore, filling of the  $t_{2g}$  levels, where screening is low, should result in a progressive shortening of the metal-ligand distance for  $OH^-$  relative to  $H_2O$ , thereby decreasing the positive entropy change for reaction (1). Table 1 shows that  $\Delta S$  decreases in going from V<sup>3+</sup>( $t_{2g}^3$ ) to Cr<sup>3+</sup>( $t_{2g}^3$ ), and the general decrease in  $K$  from Ti<sup>3+</sup>( $t_{2g}^2$ ) through V<sup>3+</sup> to Cr<sup>3+</sup> is probably due to this effect. This greater reduction in the entropy of the hydroxopenta-aquo ion relative to the hexa-aquo ion should be a maximum with the  $t_{2g}^3$  arrangement of Cr<sup>3+</sup>. With Mn<sup>3+</sup>, the next electron goes into an  $e_g$  level, increasing the screening, which should thereby increase the entropy of the hydroxopenta-aquo ion more than the hexa-aquo ion with a consequent increase in  $\Delta S$  for reaction (1); and the introduction of another electron into an  $e_g$  level with Fe<sup>3+</sup> should similarly cause a further increase in  $\Delta S$ . Table 1 confirms that  $\Delta S$  varies in this way, with a minimum at Cr<sup>3+</sup>.

As stated here, a feature of reaction (1) in this series is the constancy of  $\Delta H$  at  $\sim 10\text{ kcal mole}^{-1}$  except for Mn<sup>3+</sup>. The electronic arrangement in the  $3d$  orbitals for Mn<sup>3+</sup> is one electron short of the highly stable half-filled  $d$  orbitals in the high spin arrangement  $t_{2g}^3e_g^2$ . The ionization potentials<sup>9</sup> clearly show that this half-filled arrangement possesses high stability in the gas phase for the first transition series, and this appears also to be true in solution: for the  $M^{3+}-M^{2+}$  couple in solution, the  $t_{2g}^3e_g^2$  form is the more stable where it occurs, for example, Mn<sup>2+</sup> more stable than Mn<sup>3+</sup> and Fe<sup>3+</sup> more stable than Fe<sup>2+</sup>. Mn<sup>3+</sup> could attain this stable structure by delocalization of electrons on the ligand through orbital overlap. As the  $OH^-$  ion is more polarizable than the  $H_2O$  molecule, such a delocalization by  $sp^3-d$  overlap would tend to be greater in the hydroxopenta-aquo ion than in the hexa-aquo ion: the extra stability of the former species would result in a lower positive value for  $\Delta H$ , as found for the manganic ion. The effect will not be present in Fe<sup>3+</sup> which already has the  $t_{2g}^3e_g^2$  arrangement, and Cr<sup>3+</sup>( $t_{2g}^3$ ) is more stable in solution than Cr<sup>2+</sup>( $t_{2g}^3e_g^2$ ). The delocalization may also result in a shortening of the metal-ligand distance for  $OH^-$  which would contribute to a small extent to a lower  $\Delta S$  for reaction (1) for Mn<sup>3+</sup>. Of the  $M^{3+}$  ions in Table 1, Jahn-Teller distortions arising from the  $d_{z^2}$  and  $d_{x^2-y^2}$  orbitals might be expected only for Mn(III), probably with four short and two long metal-

Table 1

Hexa-aquo ion $M^{3+}$ : arrangement of the $3d$ electrons	$K$ at $25^\circ\text{C}$ moles litre <sup>-1</sup>	$\Delta H$ kcal mole <sup>-1</sup>	$\Delta S$ cal deg <sup>-1</sup> mole <sup>-1</sup>	$\mu$	Ref.
Ti <sup>3+</sup> $t_{2g}^2$	$1.0 \times 10^{-3}$	—	—	1.0	
V <sup>3+</sup> $t_{2g}^3$	$2.0 \times 10^{-3}$	10	20	1.0	1
Cr <sup>3+</sup> $t_{2g}^3$	$1.1 \times 10^{-4}$	9.4	13.5	1.0	2
Mn <sup>3+</sup> $t_{2g}^3e_g^2$	0.88	4.8	15.7	4.0	3
Fe <sup>3+</sup> $t_{2g}^3e_g^2$	$1.66 \times 10^{-3}$	10.2	21	1.0	4
Co <sup>3+</sup> $t_{2g}^6$	$1.35 \times 10^{-2}$	10	25	1.0	5

ligand bonds. To influence reaction (1), the distortion with the  $\text{OH}^-$  present must produce greater stability: however, relative changes in metal-ligand distances for  $\text{H}_2\text{O}$  and  $\text{OH}^-$  which might result appear from the above discussion to influence only  $\Delta S$  and not  $\Delta H$ .

As mentioned earlier,  $\text{Co}^{3+}$  is a special case, being supposed to have a low spin arrangement, whereas all the other tri-positive ions exist in the high spin state. The  $t_{2g}^6$  arrangement with low screening should be comparable with  $\text{Cr}^{3+}$  with a low value for  $K$  arising from a small positive  $\Delta S$ , but although  $\Delta H = 10 \text{ kcal mole}^{-1}$ ,  $\Delta S > 20 \text{ e.u.}$ , resulting in a value of  $K_{\text{Co}^{3+}} > K_{\text{Fe}^{3+}}$ . However, this value of  $\Delta S = 25 \text{ e.u.}$  has a large possible deviation<sup>8</sup> of  $\pm 7 \text{ e.u.}$ , which could bring  $\Delta S$  slightly less than  $20 \text{ e.u.}$  as expected for this electronic arrangement.  $\text{Co}^{3+}$  is assigned to the low spin state on the basis of its diamagnetism<sup>10</sup>, although this could be explained by  $\text{Co}^{3+}$  existing as a dimer in the condition of the magnetic measurements: there is kinetic and spectroscopic evidence<sup>11</sup> that  $\text{Co}^{3+}$  does dimerize, and this is favoured by the high concentrations used in the magnetic measurements. If dimerization is responsible for the diamagnetism and monomeric  $\text{Co}^{3+}$  has the  $t_{2g}^4 e_g^2$  arrangement,  $\Delta S$  might well be expected  $\sim 20 \text{ e.u.}$  (allowed by the error) comparable with  $\Delta S$  for  $\text{V}^{3+}$  and  $\text{Fe}^{3+}$ . However, the balance between high and low spin is obviously delicate for the cobaltic ion, and the crystal field splitting of  $\text{OH}^-$  may be just small enough in this case to ensure that the hydroxopentaaquo ion is in the high spin state, even if the monomeric hexa-aquo ion is in the low spin state. From the foregoing discussion of entropies, reaction (1) going from  $\text{Co}^{3+}(t_{2g}^6)$  to  $\text{CoOH}^{2+}(t_{2g}^4 e_g^2)$  should result in a lengthening of the metal-ligand distances with  $\Delta S$  having a high positive value, possibly  $> 20 \text{ cal deg}^{-1} \text{ mole}^{-1}$ .

### Crystal-Molecular Structure and Magnetic Properties of $\text{Cr}_3(\text{CH}_3\text{COO})_6 \cdot 3\text{H}_2\text{O}$

As part of a programme concerning magnetic exchange interaction in relatively small molecules we have largely completed an X-ray diffraction investigation of the crystal structure of  $\text{Cr}_3(\text{CH}_3\text{COO})_6 \cdot 3\text{H}_2\text{O}$ . Compounds of this type have long been thought to be trimeric and have previously been formulated as  $\text{M}_3(\text{CH}_3\text{COO})_6(\text{OH})_2 \cdot 3\text{H}_2\text{O}$  (ref. 1). We have investigated both the chromium ( $\text{M} = \text{Cr}^{\text{III}}$ ) and iron ( $\text{M} = \text{Fe}^{\text{III}}$ ) complexes and find that they are isostructural, and that the cation is trimeric and of a form suggested earlier<sup>2</sup>. We conclude, however, that for these compounds ( $\text{M} = \text{Cr}^{\text{III}}$  or  $\text{Fe}^{\text{III}}$ ) the correct formulation is  $\text{M}_3(\text{CH}_3\text{COO})_6 \cdot 3\text{H}_2\text{O}$ .

Crystals of  $\text{Cr}_3(\text{CH}_3\text{COO})_6 \cdot 3\text{H}_2\text{O}$  are orthorhombic, space-group  $P2_12_12$  with  $a = 13.7 \text{ \AA}$ ,  $b = 23.2 \text{ \AA}$ ,  $c = 9.2 \text{ \AA}$  and  $Z = 4$  molecules per unit cell. Atom co-ordinates have been determined from Patterson and Fourier techniques based on about 1,800 independent observed reflexions and have been partially refined by least squares

methods. The  $R$  factor at the present stage of refinement is 0.16.

While there is no constraint imposed by crystal symmetry the complex ion has  $3/m$  point group symmetry; the chromium atoms lie at the apices of an equilateral triangle of edge  $3.28 \text{ \AA}$  and each is octahedrally co-ordinated by oxygen atoms. The three octahedra share a common vertex which is coplanar with, and at the centre of, the triangle of chromium atoms. A single oxygen atom occupies this shared vertex; the vertex of each octahedron *trans* to the shared vertex is occupied by a water molecule. The four remaining vertices of each octahedron about the chromium atoms are occupied by four oxygen atoms, one from each of four different carboxyl groups. The carboxyl groups thus form bridges between adjacent vertices of adjacent octahedra. The co-ordination of the metal atoms and the bridging arrangement are illustrated in Fig. 1. At the present stage of refinement the observed Cr-O distances range from  $1.9 \text{ \AA}$  to  $2.1 \text{ \AA}$  with a mean value of  $2.0 \text{ \AA}$ .

Fig. 1. Stereochemistry of the trinuclear ion  $[\text{Cr}_3(\text{CH}_3\text{COO})_6 \cdot 3\text{H}_2\text{O}]^+$

The magnetic susceptibility of this compound has been reported over a very wide range of temperature ( $-0.35^\circ \text{K}$ – $300^\circ \text{K}$ ; refs. 3 and 4) and values for the range  $80^\circ \text{K}$ – $300^\circ \text{K}$ , which have been obtained in this laboratory<sup>8</sup>, confirm the earlier work. The complex is a model one for the investigation of magnetic exchange in a trinuclear system and its magnetic behaviour has been explained by earlier workers by means of the spin Hamiltonian<sup>3,4,6,7</sup>:

$$H = J_0(S_1 \cdot S_2 + S_1 \cdot S_3) + (J_0 + J_1)S_2 \cdot S_3$$

where  $S_1$ ,  $S_2$  and  $S_3$  are the spins of the three chromium atoms (each  $3/2$ ), and  $J_0$  and  $J_1$  are the exchange integrals. The calculated values are  $J_0 = 30^\circ$  and  $J_1 = 7.5^\circ$  but the evaluation of  $J_1$  is rather uncertain. The observed trigonal symmetry of the cation requires  $J_1 = 0$ , which value is reasonably consistent with the magnetic data but is not consistent with the heat capacity of the compound at very low temperature<sup>6</sup>. It is not unlikely, however, that a very small amount of magnetic exchange between different trimeric units, which is suggested by the magnetic results<sup>4</sup>, may account for the heat capacity data.

For the isostructural iron complex the unit cell dimensions are  $a = 13.0 \text{ \AA}$ ,  $b = 23.0 \text{ \AA}$ ,  $c = 9.0 \text{ \AA}$ . This compound also shows magnetic exchange and  $J_0$  has been reported from earlier results<sup>6</sup> to be about  $40^\circ$ . The magnetic results obtained in this laboratory<sup>8</sup> both for the

iron and for the chromium complexes will be reported elsewhere as will the complete structural details for the chromium complex.

### Cathode-ray Polarography with Rapid-dropping Mercury Electrodes

LINEAR sweep cathode-ray polarography with the dropping mercury electrode has developed in two distinct lines: single sweep polarography<sup>1-3</sup> in which the applied potential change is impressed on the electrodes once in the lifetime of each mercury drop, and multisweep polarography<sup>4-6</sup> in which it is applied several or many times. The latter is electronically the simpler, but the former possesses distinct advantages and is in more general use. In order to ensure that the drop surface area does not change appreciably during the electrode reaction, it is necessary, in the case of single-sweep working, to synchronize the application of the potential with the latter part of drop life. In earlier instruments this is achieved by using a multivibrator with fixed 'rest' and 'sweep' periods and arranging for the sharp decrease in current, which occurs when a drop detaches, to trigger the instrument back to its 'rest' condition while growth of the next mercury drop takes place. Later instruments<sup>7,8</sup> use a more satisfactory arrangement by which the drop is detached by the application of an electromechanical pulse to the electrode capillary at the conclusion of the potential sweep.

Recently we have investigated a new method of cathode-ray polarography using dropping mercury electrodes of very short drop time. Using a transistorized timing unit and drop controller, described elsewhere<sup>9</sup>, we have been able to achieve fast drop rates with accurate control. Electrodes with drop times as short as 0.08 sec have been produced in this way and these have been used in conjunction with a Southern Analytical cathode-ray polarograph. Polarographic reductions at an electrode of this type do not produce the characteristic cathode-ray polarographic wave (Fig. 1); but instead a step is obtained similar to that of conventional polarography. A typical example of this is shown in Fig. 2.

Cathode-ray-type waves arise from a combination of two processes. When the applied potential reaches a value equal to that of the characteristic reduction potential of the reacting species, all that species in the immediate vicinity of the mercury drop surface is 'stripped out' of solution (or reacted at the drop surface) by a process that is not diffusion-controlled and not governed by the Ilkovic equation. It gives rise to an initial current of a magnitude greater than the limiting diffusion current. However, once this process is complete the reaction can only continue if the depleted layer around the mercury drop is replenished with the reacting species. Under polarographic conditions this can only take place by the normal processes of diffusion, so that the current falls to the limiting diffusion current, or in practice, often to a value below this. The wave shown in Fig. 1 therefore results.

Fig. 1. Linear sweep (single sweep) cathode-ray polarograph. 1  $\mu$ g lead/ml. in M potassium chloride. Sensitivity factor  $1 \times 10^3$ . Start potential, 0.35 V

Fig. 2. Linear sweep cathode-ray polarograph; rapid-dropping mercury electrode. 1  $\mu$ g lead/ml. in M potassium chloride. Dropping mercury electrode drop time, 0.08 sec; sensitivity factor  $1.5 \times 10^3$ ; half-wave potential 0.42 V versus saturated Ag/AgCl electrode

Both 'stripping' and 'limiting diffusion' processes are operating in any polarographic reduction, but a high ratio of rate of change of applied potential to drop time favours the appearance of the stripping peak. The undamped, high-speed response of the cathode-ray tube is also a factor in the presentation of this wave-form. In conventional polarography the ratio is reversed. The ratio of drop time to rate of change of applied potential is high, so that the 'stripping' peak is suppressed and the conventional step appears. The damped indicating or recording system also makes some contribution to this. This interpretation on the basis of potential sweep rate-drop time ratios is supported by the work of Smith<sup>10</sup>, who has produced cathode-ray-type waves with a conventional polarograph by using dropping mercury electrodes with drop time in some cases as long as 8 min. Such drop times bear a ratio to the rate of change of applied potential similar to that of conventional polarography. Cathode-ray-type waves also result when mercury pool micro-electrodes are used.

In the work recorded here the total sweep time used was 2 sec for a change of 0.5 V (0.25 V per second), so that 25 drops form, and are detached, during the sweep period. This establishes a ratio similar to that of conventional polarography, so that waves of 'conventional' shape would be expected. The results of our investigations are considered to add further support to the foregoing interpretation.

This type of polarography has a number of advantages, especially those connected with the rapidity of the polarographic determination. A reversible polarographic wave of conventional shape is produced on the screen in less than 2 sec, which should lead to many applications to kinetic investigations and high-speed polarography for industrial control. There is a loss in sensitivity compared with single sweep cathode ray polarography<sup>11,12</sup>, due to the very small area of the 0.08-sec mercury drops used. The sensitivity obtained in practice is, however, much greater than that calculated, presumably due to stirring at the drop surface caused by the pulse required to detach the drop. The detachment of such small drops was found to require a comparatively large amount of energy. Our experiments have shown that the sensitivity obtainable is at least equal to a conventional polarograph.

High-sweep linear sweep cathode-ray polarography of this type may be carried out with any linear sweep cathode-ray polarograph by the addition of a suitable drop control system. The later Southern Analytical polarographs are particularly suitable for this, since a control relay is already incorporated in the electrode stand. It is only necessary to disconnect this relay from the instrument synchronization circuit and to connect it to a drop timer of suitable period. Modification of the control circuits of the above instrument to give variable drop times might not be difficult and is worth consideration. Instruments of this complexity are, however, not strictly necessary, since the essential requirements are only a simple saw-tooth generator of suitable period, a drop timer and electrode stand with a drop-control relay and a cathode-ray oscilloscope.

### $\beta$ -Sorption Complexes of Hydroxy-salts

MANY lamellar substances form interlamellar sorption complexes with polar molecules. These may be  $\alpha$ -complexes, in which the molecules lie flat on the sorbent layers, or  $\beta$ -complexes, in which the molecules are upright with respect to the layer<sup>1</sup>. Such complexes have been examined with graphitic acid<sup>2,3</sup>, montmorillonite<sup>4</sup>, and nickel cyanide<sup>5</sup>.

In the present communication, an investigation is reported of the  $\beta$ -type interlamellar complexes formed by hydroxy-salts of zinc<sup>6</sup> with straight chain amines. The substances used were hydroxysulphate (HS) 4/1, HS 3/1, hydroxychloride (HC) 6/1, HC 4/1, and hydroxychlorosulphate (HCS) 5/1/2.

Fig. 1. Spacing variations for HS 4/1 (on left, top scale of C numbers) and HC 6/1 (on right, bottom scale). In both cases, substance dried at room temperature. ●, HS 4/1; ○, HC 6/1.

The results are influenced by the method of drying the hydroxy-salt, and we report results for the substances dried at 60° C and at room temperature. As usual, the results are shown in the form of graphs giving spacing as a function of number of C atoms in the chain.

Taking first the results for the substance dried at room temperature, the first four substrates show very similar tendencies, for 4–8 C atoms. The HCS gives a smaller slope, due perhaps to the fact that this substance is more complex<sup>7</sup>. The similarity of the slopes is attributed to the fact that the shorter-chain amines are highly polar, and their sorption energy more than compensates for the inter-layer interaction energy; thus small differences in the lattice energies of the substrates are not shown up. Examples of curves are shown in Fig. 1.

The second part of the graphs, for molecules having more than 8 C atoms, shows more marked differences. The basal spacing of the most basic substrates, HS 4/1 and HC 6/1, has a steeper slope than that given by the less basic substances, HS 3/1 and HC 4/1.

This may be due to the fact that the latter two compounds have a more ordered structure than the first two, and so a greater inter-layer energy (that is, a lower energy state). Further, the polarity of the longer-chain amines is less, the sorption is thus less energetic, and differences appear between the substrates.

With the hydroxysulphates, two types of spacing appear, possibly corresponding to different inclinations of the molecules. This phenomenon has not been observed with the hydroxychlorides, except for isolated cases. The HCS gives irregular results, with three spacings in some cases.

With the salts dried at 60° C (Fig. 2), all the graphs follow the same trend up to 8 C atoms. Beyond this point, a separation occurs. The HS 4/1 gives a completely distinct graph. In all cases, the slope of the line is less the more crystalline the compound is, and the less basic.

Fig. 2. Spacing variations for substances dried at 60° C. ●, HS 4/1; ×, HS 3/1; ○, HC 6/1; △, HC 4/1; ◇, HCS 5/1/2

From the slope of the graphs, the orientation and quantity of molecular layers can be deduced. In general, the slope is of the order of 2.3–2.9 Å/C atom, indicating two erect layers of molecules; but for certain substances, HC 6/1, HS 4/1 (at room temperature) and HCS (at 60° C), a slope of 3.5–3.9 is found, possibly due to the existence of three erect layers.

With alcohols, the hydroxy-salts form  $\beta$ -complexes with difficulty, and only in isolated cases. Aromatic substances (anthranilic acid, hippuric acid, naphthol yellow and others) give large-spacing  $\beta$ -complexes.

## RADIATION CHEMISTRY

### Short-lived Radicals in Irradiated Glycine

SEVERAL investigators have used the electron spin resonance technique to measure the numbers of stable free radicals induced by ionizing radiation in amino-acids<sup>1–4</sup>. The observation that at doses in the M.rad region the radical yield does not increase linearly with the absorbed dose but tends towards saturation was explained by Rotblat and Simmons<sup>4</sup> as being due to a

back reaction between stable and unstable radicals, but as their nature was still in some dispute at that time no details of the mechanism were attempted. The availability of new evidence concerning the radical species has now prompted further investigation of this problem.

If the electron spin resonance measurements can be made only after the irradiation has been completed, it is not possible to observe radicals with life-times less than about 10 sec at room temperature. In some cases, however, it may be possible to stabilize such radicals by irradiating at low temperatures, and this has been done by Henriksen for frozen aqueous solutions of glycine<sup>5</sup>. He was thus able to show that the water component gave rise to OH radicals plus an unidentified species, while the glycine gave rise to  $^+NH_3CHOO^-$  and  $-CH_2COO^-$ . Very recently the use of carbon-13 has enabled this proposal to be confirmed for pure glycine<sup>6</sup>. It seems likely that these were the radicals detected by ultra-violet absorption during the pulse radiolysis of glycine solutions at room temperature<sup>7</sup>.

Since these organic radicals retain their specific orientation within the molecule after their formation<sup>8</sup>, it seems unlikely that they can move at all in the dry powder. Hence the reactive transients must be the unobserved fragments, namely,  $NH_3^+$  (complementary to  $-CH_2COO^-$ ) and  $\dot{H}$  (complementary to  $^+NH_3CHOO^-$ ). Ammonia formed from the neutralization of  $NH_3^+$  was not detected at room temperature, but it was observed when the powder was heated to 120° C (ref. 9). This effectively eliminates  $NH_3^+$  as the attacking radical as it could not be sufficiently mobile at room temperature. It therefore seems most probable that hydrogen atoms are the reactive species in the solid material. If this is true, then not only can each  $\dot{H}$  attack and neutralize one of the observable radicals, but it can also react with another  $\dot{H}$  to form molecular hydrogen which should then be detectable after irradiation of glycine. Accordingly an experiment was devised to test this hypothesis.

A sample consisting of 1 g of dry 'AnalaR' grade glycine was evacuated to  $5 \times 10^{-5}$  torr in a glass tube and sealed. It was then irradiated with 50 M.rads using the 15-MeV electron linear accelerator at St. Bartholomew's Hospital, London. Afterwards the sample tube was connected to a mass spectrometer (Associated Electrical Industries Type MS 10) tuned to mass number 2, and the vacuum seal opened. A large positive reading was obtained, from which it was concluded that about  $3 \times 10^{-7}$  g, corresponding to about  $10^{17}$  molecules, had been present. A check with unirradiated glycine was completely negative, while a check on an empty glass sample tube given 50 M.rads showed a signal the amplitude of which was just a few per cent of that from the glycine. It was thus confirmed that hydrogen is a product of irradiated glycine, and accordingly it is concluded that atomic hydrogen is the reactive, short-lived radical previously postulated<sup>4</sup> to account for the shape of the yield-dose curves for stable radicals.

I thank Prof. J. Rotblat for the use of the linear accelerator, and Mr. D. J. Pacey of Brunel College for his assistance with the mass spectrometer measurements.

## BIOPHYSICS

Inhibition of Cell Division in *Escherichia coli* by Electrolysis Products from a Platinum Electrode

In an investigation of the possible effects of an electric field on growth processes in bacteria, we have discovered a new and interesting effect. In *E. coli*, the presence of certain group VIIIb transition metal compounds in concentrations of about 1–10 parts per million of the metal in the culture medium causes an inhibition of the cell division process. The bacteria form long filaments, up to 300 times the normal length, which implies that the growth process is not markedly affected.

Experiments were performed in a continuous culture apparatus in a chamber of special design. The nutrient medium was the chemically defined 'C' medium of Roberts *et al.*<sup>1</sup> used with 1 g of glucose/l. and 0.026 g/l.  $MgCl_2$ . The chamber was maintained at  $37^\circ \pm 0.1^\circ C$ . *E. coli* B and K-12 were used to inoculate the chamber. Compressed air was bubbled through a glass frit bubbler. Two half-cylindrical platinum mesh electrodes were built into the chamber. Once the bacterial population reached a steady state (about 24 h) as determined by turbidity measurements, it maintained its constant value ( $\pm 2$  per cent transmission for a 5-fold dilution of the effluent) for a period of 10–14 days. All experiments were performed within 10 days after inoculation.

The resistance of the chamber was approximately 6 ohms. An audio oscillator was the source of sinusoidal voltages of 50–10<sup>5</sup> c/s. This was fed into a conventional audio power amplifier and then to the platinum electrodes. The voltage and current were monitored with a dual beam oscilloscope.

On turning the electric field on at 1,000 c/s, 2 amp (peak to peak) through the chamber, the turbidity began to decrease after 1 h. (Platinum was chosen for the electrode material because of its well-known chemical inertness, and 1,000 c/s was chosen to eliminate electrolysis effects and electrode polarization. As we will show, both are mistaken ideas which led, via serendipity, to the effects described in this communication.) After 2 h, 'washout' of the bacteria was imminent and the voltage was turned off. After 8 h the population density had returned to its previous value. This process could be repeated. Microscopic examination of the effluent from the chamber showed that the *E. coli* ceased dividing (disappearance of 'waists') within 1–2 h after the current was turned on, and began to elongate. Within a few hours, all bacteria were in the form of long filaments, the length of which increased rapidly with time. For 1–2 h after the removal of the voltage, the cells continued to increase in length. Thereafter, however, the fairly uniform appearance of the bacteria under the phase contrast microscope changed. The darker material segregated into normal sized segments over the full length of the filament, leaving small, light grey gaps between segments. 'Waists' began to form in the gaps, and cell division occurred shortly thereafter over the length of the filament.

A frequency of the applied voltage of 500 c/s is very effective in causing filamentous growth. The efficiency decreases as the frequency increases, until at 6,000 c/s no filaments can be seen and no change in turbidity occurs over 24 h of application. From 6,000 c/s to 10<sup>5</sup> c/s no effects can be detected within 24-h trials. Increasing the current at a given frequency increases the size of the filaments appearing within a given time and causes a faster decline of the turbidity. We have found that oxygen is required to cause the effect; with nitrogen or helium bubbled through the cell, no effect of the electric field can be detected at all.

A number of physical and chemical agents are known to cause filamentous growth, that is, inhibit cell division but not growth. Among these are dyes such as methylene blue<sup>2</sup> and penicillin<sup>3</sup>, near ultra-violet irradiation<sup>4</sup>, transfer to an unaccustomed medium, osmotic pressure changes, temperature changes<sup>5</sup>, and magnesium deficiency or excess<sup>6</sup>.

We have, with a variety of tests, eliminated the possibilities that ultra-violet light, temperature, pH, and magnesium concentration are involved in this effect of the electric field. We have also found that adaptive mechanisms and mutation effects are not involved.

It is possible that a chemical change is produced in the medium by electrolysis and that these new chemical products are the causative agents. To test this the nutrient was pumped into one chamber with electrodes in it (electrolysis chamber) before pumping it into a second chamber without electrodes which had been inoculated (bacterial chamber). The electric current was passed through the electrolysis chamber. No electric current was present in the bacterial chamber. If a new chemical species is created in the electrolysis chamber and it has a sufficiently long life it will appear in the bacterial chamber. The test conclusively showed that one or more long-lived new chemical species was created by the electric current and is responsible for the bacterial elongation. It caused elongation if oxygen was present in the electrolysis chamber regardless of what gas was bubbled through the bacterial chamber. Helium bubbled through the electrolysis chamber produced no elongation in the bacterial chamber. The active agent was not an insoluble gaseous product, since transferring the gas bubbling through the electrolysis chamber into the bacterial chamber caused no effect, if the medium was not also transferred.

A suspicion that an oxidizing agent was being generated by electrolysis was investigated by using a potassium iodide–starch test solution. Ordinary medium gave no reaction. The electrolysed medium gave a definite positive test—the blue colour developing after about 5 min and going through yellow and orange intermediate states. The time course of the development of the concentration of this new agent in the electrolysed medium was strikingly parallel to the time course of the elongation processes. The concentration was proportional to the electric current. It decreased as the frequency increased from 500 to 6,000 c/s, at which frequency it was not detectable. All these measurements strongly implicate this new chemical as the causative agent.

Given the chemically defined 'C' medium, a number of oxidizing agents are conceivably created during electrolysis. The following ions or molecules were looked for with appropriate sensitive qualitative tests:  $ClO^-$ ,  $ClO_2^-$ ,  $ClO_3^-$ ,  $ClO_4^-$ ,  $H_2O_2$ ,  $NH_2OH$  and  $S_2O_8^{2-}$ . None of these was detected. Some oxidizing agents were tested by inoculation directly into the bacterial continuous culture chamber. These were:  $H_2O_2$ ,  $NH_2OH$ ,  $ClO^-$ ,  $N_2O$  (gas),  $NO$  (gas) and  $NO_2^-$ —all in appropriate quantities below that at which killing occurred. None of these chemicals caused elongation.

Each component of the 'C' medium was then made up in an appropriate concentration and electrolysed for 6 amp-h. The resultant solution was tested with the potassium iodide–starch solution. Negative results were obtained with the following:  $PO_4^{3-}$ ;  $SO_4^{2-}$ ;  $PO_4^{3-} + \text{glucose}$ ;  $PO_4^{3-} + SO_4^{2-} + \text{glucose}$ ;  $Na_2SO_4$ ;  $Na_2CO_3$ . Positive tests were obtained with the following:  $(NH_4)_2SO_4$ ;  $(NH_4)_2CO_3$ ;  $NH_4Cl$  and chlorides. A faint positive response was obtained with  $NaCl$ . Only solutions with chlorides showed the intermediate yellow to orange to blue transitions. It is known that platinum electrodes can be attacked by an acidified chloride solution during electrolysis (to form  $[PtCl_6]^{2-}$ ) (ref. 7). We therefore suspected that a soluble platinum salt was the active agent. A solution of  $(NH_4)_2PtCl_6$ , when tested with the potassium iodide–

starch test, produced an exact duplication of the results with the electrolysed medium, if the platinum was present in a concentration of greater than 100 p.p.m. Inoculating the bacterial continuous culture chamber with a solution of  $(\text{NH}_4)_2\text{PtCl}_6$  so as to maintain a concentration in the chamber of Pt (IV) 10 p.p.m. over 2 h caused filaments to appear. This verified that the platinum salt was indeed an active agent. Quantitative tests for platinum IV in the electrolysed medium ( $\text{SnCl}_2$  test) showed that under our standard test condition (1,000 c/s, 3 amp) the steady-state concentration of the metal was 8 p.p.m. and was reached in about 2 h.

We have now tested a number of platinum and other group VIIIb compounds to determine the most effective anions and cations for this effect. The chemicals were inoculated so as to maintain a concentration of 8 p.p.m. of the metal in the nutrient medium of the cell for a period of 2 h. The effects fell into three categories: the bacteria were killed; there was no apparent change; a minimum of 20 per cent of the bacteria were forced into a filament form. These results are given in Table 1. The generalizations to be derived from these results are minimal. Platinum is not the only metal capable of inhibiting cell division, and in fact we have found that rhodium is as effective as platinum. We cannot at this time specify the relative effectiveness of the various metallic oxidation states or the effects due to various ligands and their spatial arrangements about the metal.

Table 1. EFFECTS OF GROUP VIIIb TRANSITION METAL COMPOUNDS ON BACTERIAL GROWTH (CONCENTRATIONS OF METAL IONS MAINTAINED FOR 2 H AT 8 P.P.M. IN THE CONTINUOUS CULTURE CHAMBER)

A. Caused bacterial death	B. Caused no change	C. Caused elongation
$\text{CoCl}_2$	$[\text{Co}(\text{NH}_3)_6]\text{Cl}_2$	$\text{K}^+, \text{NH}_4^+, \text{H}^+ - [\text{PtCl}_6]^-$
$(\text{NH}_4)_2\text{IrCl}_6$	$\text{K}_2\text{Ir}(\text{NO}_2)_6$	$(\text{NH}_4)_2\text{PtBr}_6$
$\text{NiCl}_2$	$[\text{Ni}(\text{NH}_3)_6]\text{Cl}_2$	$(\text{NH}_4)_2\text{PtI}_6$
$(\text{NH}_4)_2\text{OsCl}_6$		$[\text{Pt}(\text{en})_3]\text{Cl}_4$
$(\text{NH}_4)_2\text{PdCl}_6$	<i>Cis</i> and <i>trans</i> $[\text{Rh}(\text{en})_3]\text{Cl}_2\text{NO}_2$	$\text{RhCl}_3$
$[\text{Rh}(\text{NH}_3)_6]\text{Cl}_3$		$(\text{NH}_4)_2\text{RhCl}_6$
$\text{PdCl}_2$		$[\text{Ru}(\text{NH}_3)_6]\text{ClO}_4\text{Cl}$

We believe the evidence is fairly conclusive that various group VIIIb transition metal ions in concentrations of 1–10 p.p.m. can inhibit cell division in *E. coli* while not apparently interfering with growth. Many questions arise from this work that we are now attempting to answer, such as: What is the mechanism of action of these metal ions? Where is the locus of action in the bacterial cell? How does the effect of these metal ions relate to the actions of the other causative agents of filamentous growth—is there a weak link that all operate on? Can these metal ions inhibit cell division in other bacteria, or cells?

We thank Prof. Jaroslav Drobnik of Charles University, Prague, and Prof. Harold Sadoff of Michigan State University, for their advice, and Mr. Alan Stemler and Mr. Paul Vignola for their very able assistance with the experiments. This work was wholly supported by U.S. Public Health Service grant GM-10890.

## BIOCHEMISTRY

### Ethylene Production and Lipid Mobilization during Germination of Castor Beans

RECENT investigations<sup>1</sup> have shown that ethylene is evolved during the germination of oat seeds and *Penicillium digitatum* spores. This article reports investigations conducted with a germinating fatty seed, the castor bean (*Ricinus zanzibarensis*). Ethylene production and lipid levels were determined at various stages, and these values will be discussed with relation to the activity of the glyoxylate pathway enzymes<sup>2</sup> and the changes in mitochondria<sup>3</sup> during the germination of the seeds.

When castor beans (20 per run) were germinated under aseptic conditions at room temperature in the light, analysis for ethylene<sup>4</sup> showed that they were active producers of this gas, and that they exhibited several peaks in the rate of its evolution (Table 1). To minimize the uneven development, three days after wetting the seeds twenty of those showing signs of germination were selected for measurement of subsequent ethylene evolution. To determine the ethylene production during the first few days after wetting, separate gas collections were made from flasks containing twenty seeds, whether or not the seeds germinated. The first peak in ethylene production occurred on the third day after wetting of the seeds, and coincided with the cracking of the seed coat. This evolution may indicate the presence in the seed of preformed ethylene, the gas being forced out on hydration of the seed, or it may reflect an actual formation of the gas on activation of enzymatic or chemical systems during germination. The second peak, at nine to ten days, was about twice as great as the first, and coincided with the rapid elongation of the seedling after its emergence from the seed coat. The third peak was on the fourteenth and fifteenth days, at full separation of the leaves from the cotyledons and, like that of the tenth day, was at a period of very rapid growth. (The maximum value was 2.9 ml./h/seedling, compared with that from oats, about 0.2 ml./h/seedling.) Thereafter, rates of production of both ethylene and carbon dioxide decreased. A close correlation between the changes in rates of production of the two gases existed through the germination period.

Table 1. LIPID CONTENT AND PEAKS IN ETHYLENE PRODUCTION OF GERMINATING CASTOR BEANS

Days*	$\text{C}_2\text{H}_4$ (ml./24 h/bean)	Per cent ether soluble (dry weight basis)
3	22, 24	36.5
9–10	35, 39	12.5
14–15	68, 73	8.4

\* After wetting of seeds.

Results for ethylene are given for 2 separate runs.

A rapid breakdown of ether-soluble material began between the third and fourth days, and by the tenth day the lipids had reached a low level (Table 1), as observed by a number of other workers. Carpenter and Beevers<sup>5</sup> have reported that isocitritase, one of the key enzymes of the glyoxylate cycle, shows maximum activity in germinating castor beans at the time of most rapid fat breakdown (the sixth day after wetting), and that it then declines in activity as the lipid degradation decreases. Since we found ethylene production to be at a maximum during this later stage, it would appear that the functioning of the glyoxylate pathway does not enhance ethylene evolution. That operation of the complete pathway is not essential to the production of ethylene is evident from the fact that the gas is produced by animal tissues<sup>6,7</sup>, which apparently do not possess all the glyoxylate cycle enzymes.

In our earlier<sup>8</sup> work with sub-cellular particles from tomatoes we showed that the ethylene-producing system was activated by disintegration of the particles, and pointed out the possible relationship of this to the reported<sup>9</sup> disintegration of mitochondria as fruits ripen. Akazawa and Beevers<sup>3</sup> found that mitochondria from the endo-

sperms of castor beans, during the first five days of germination, increased in amount and in  $q_{01}$  values and had P/O ratios greater than 2; three days later all these values were markedly lower. In 9–10 days the endosperm tissue had completed a cycle of activation, growth and ageing, and it is possible that destruction of mitochondria with ageing is reflected in the high ethylene values.

### Inhibition of Intestinal Amino-acid Transport by Sugars

GALACTOSAEMIA, an inborn defect of galactose metabolism, is known to be associated with derangements in the renal tubular transport of amino-acids<sup>1</sup>. It is of interest that some of the features of this disease, including amino-aciduria, can be reproduced in rats by feeding them a diet containing 30 per cent galactose<sup>2</sup>. Recently, Segal *et al.*<sup>3</sup> have shown that the uptake of certain amino-acids by rat kidney slices can be inhibited *in vitro* by galactose and fructose at relatively low concentrations (5–6 m molar), while at a higher concentration (16–8 m molar) glucose also exerts some inhibitory effect. Since in the mammalian organism many of the transport processes of the kidney and the small intestine appear to be similar we have examined the effect of sugars, especially galactose, on the transport of amino-acids by the small intestine of the rat.

Male Sprague-Dawley rats weighing 120–150 g were fasted overnight. Six everted segments from the distal jejunum and proximal ileum, each measuring 3–5 mm, were incubated under 95 per cent oxygen and 5 per cent carbon dioxide in 5 ml. of Krebs-Ringer bicarbonate buffer (pH 7.4). Each amino-acid was examined at a concentration of 5 mmoles/l. The specific activity was 0.02  $\mu\text{C}/\mu\text{mole}$  except in the case of hydroxyproline where it was 0.1  $\mu\text{C}/\mu\text{mole}$ . All amino-acids were in the L form (except glycine) and were uniformly labelled with carbon-14 except for hydroxyproline which was labelled with tritium at the 5 position. The sugars when added

to the medium were present at a final concentration of 28 mM. After incubation for 60 min, the segments were removed, blotted, and boiled for 5 min in 2 ml. of water. The transfer of amino-acids was expressed as the distribution ratio of amino-acid in intracellular fluid to that in the medium as described by Rosenberg *et al.*<sup>4</sup>. Extracellular fluid volume was measured with <sup>14</sup>C-inulin and total water content of the segments by drying to constant weight at 110° C.

The results are shown in Table 1. Glucose, xylose, and ribose caused no inhibition of amino-acid transport while galactose caused a significant depression in the transport of alanine ( $P < 0.001$ ), valine ( $P < 0.001$ ), glycine ( $P < 0.001$ ) and hydroxyproline ( $P < 0.02$ ). Lysine transport was inhibited at a  $P$  value of  $< 0.5$  and while not statistically significant it should be noted that the transport of lysine in the absence of hexose was low and thus any depression of its transport would be difficult to demonstrate. It will be seen that fructose at the same concentration also inhibited alanine ( $P < 0.001$ ) and hydroxyproline ( $P < 0.001$ ) uptake but the transport of other amino-acids was not inhibited.

We also examined the effects of feeding Sprague-Dawley rats a diet containing 30 per cent galactose for 2–3 months. All the galactose-fed rats developed cataracts. The litter-mate controls were fed the same food but without added galactose. Intestinal slice experiments were carried out as above and distribution ratios calculated. No sugars were added to the incubation medium. In the galactose-fed rats there was a significant depression in the intestinal transport of all the amino-acids tested (Table 2).

The *in vitro* inhibition of amino-acid transport by galactose, and sometimes by fructose, in the gut of the rat cannot be explained by a water shift. There was no significant difference between the <sup>14</sup>C-inulin space in the segments incubated without added sugar and in those incubated in the presence of any of the sugars tested. Recently, Newey and Smyth<sup>5</sup> reported that galactose inhibited and glucose enhanced the transfer of glycine and methionine in everted rat gut sacs. In contrast to these authors we did not observe any enhanced transfer of amino-acids in the presence of glucose, and, in addition, we found some inhibition with fructose. Our results with intestinal slices are therefore more in keeping with those reported by Segal *et al.* with kidney cortex slices<sup>3</sup>. Like Newey and Smyth<sup>5</sup> we did find that when galactose transport was inhibited by phlorrhizin, the observed influence of galactose on amino-acid transport was prevented.

The results in rats fed 30 per cent galactose show that these animals develop a defect in amino-acid transport in the intestine as well as in the kidney. This *in vivo* defect involved amino-acids of three different transport

Table 1. THE EFFECT OF SUGARS ON THE *in vitro* TRANSPORT OF AMINO-ACIDS BY RAT INTESTINAL SLICES

Addition to medium*	Distribution ratios†				
	L-Alanine	L-Valine	Glycine	L-Lysine	Hydroxy-L-proline
None	4.9 ± 1.0 (16)	4.1 ± 0.3 (11)	2.0 ± 0.3 (8)	1.3 ± 0.2 (6)	2.0 ± 0.3 (8)

\* Ratios shown are means ± S.D. with the number of determinations in parentheses.

'groups' and is also observed *in vitro* when galactose is added to intestinal slices. In view of the fact that glucose and galactose are mutually inhibitory with regard to their transport across the intestine, competitive inhibition of amino-acid transport by galactose seems unlikely as one would then expect glucose to inhibit as well. One could argue that either the transport of the hexoses or their phosphorylation in the intestinal cell might result in a drop in the mucosal levels of adenosine triphosphate (ATP). We measured ATP levels in intestinal slices of rats fed 30 per cent galactose and in controls. The mean ATP level in the galactose-fed rats was 0.492  $\mu$ moles/g and in the controls 0.637  $\mu$ moles/g ( $P < 0.05$ ). While these results are significant and of interest they do not allow us to conclude that the decrease in ATP levels is primarily involved in the impairment of amino-acid transport. Since phosphorylation of galactose and fructose occurs in the intestine and since phosphorylated sugars may inhibit enzymes such as phosphoglucomutase<sup>1</sup>, the accumulation of hexose phosphates may also be a factor in the derangement of amino-acid transport.

The precise mechanism for the inhibiting effect of galactose on amino-acid transport remains to be determined. However, on the basis of the investigations presented, it would appear likely that in the human disorder of galactosaemia there may be a defect in the transport of amino-acids not only in the kidney but also in the intestine.

### Inhibitory Effect of Progesterone on the Activity of Human Myometrial Actomyosin Adenosinetriphosphatase

In the previous communication<sup>1</sup> from this laboratory it was noted that progesterone in concentrations of more than 10  $\mu$ g (and up to 50  $\mu$ g tested) per mg wet weight human non-pregnant myometrial tissue inhibits the human myometrial ATPase activity on an average of 27.3 per cent ( $P < 0.001$ ) based on fifteen experiments. On the other hand, oestradiol in fourteen cases in similar concentrations, as for progesterone showed only an average reduction of 5.8 per cent ( $P < 0.01$ ) on ATPase activity<sup>2</sup>.

In order to make sure that this inhibitory effect of progesterone is not entirely on the non-actomyosin fraction of the homogenate, actomyosin was extracted using 0.5 M potassium chloride and ATP according to the procedure described by Csapo<sup>3</sup>. The ATPase activity of the human myometrial actomyosin was determined according to the procedure described before<sup>1</sup>. The amount of inorganic phosphorus liberated/mg nitrogen actomyosin/min at 37°C was taken as a measure of ATPase activity. The results of eleven non-pregnant and three pregnant human samples are shown in Table 1.

Table 1

Number of cases	Average $\mu$ moles of phosphorus liberated/mg N <sub>2</sub> actomyosin/min incubation		Average reduction in phosphorus liberated ( $\mu$ moles)
	Control	Progesterone 7.46/ mg N <sub>2</sub> actomyosin	
11 non-pregnant	0.092	0.074	0.018 (19.6%)*
3 pregnant	0.047	0.034	0.013 (27.6%)
* $t = 5.13$			
$P < 0.001$			

In conclusion it can be said, based on the results described, that progesterone has a definite inhibitory effect on the human myometrial actomyosin ATPase activity.

### Binding of Thyroxine and Triiodothyronine by Heart and Pituitary Proteins

THE presence of thyroxine-binding activity in extracts of muscle tissues<sup>1</sup> and in extracts of mouse thyrotropic and mammotrophic pituitary tumours<sup>2</sup> has been demonstrated by observing the migration of radioactive thyroxine with the proteins in question during electrophoresis on paper at pH 8.6. The work recorded here on the relative affinity of water-soluble human heart and pituitary proteins for thyroxine (T<sub>4</sub>) and triiodothyronine (T<sub>3</sub>) made use of an independent binding assay.

The tissues were selected at autopsy, which was performed no later than 2 h after death. Every effort was made to obtain heart muscle and pituitary tissue that seemed to be unaffected by disease. (Death in all cases was associated with cancer.) The tissues were chilled immediately after collection, and were kept at 4°C throughout preparation. Pooled samples were used in all experiments.

Protein fractions were prepared by homogenizing small pieces of water-washed tissues from which visible fat and fibre had previously been removed. About 5 ml. of water was used per g of tissue homogenized. Insoluble material was separated by centrifugation and discarded.

In order to remove any T<sub>4</sub> or T<sub>3</sub> bound to the tissue proteins, each supernatant of about 50 ml. was dialysed at 4°C in a cellulose casing against two 6-l. changes of distilled water, one 6-l. change of 0.05 M acetic acid (pH 3.0), and another two 6-l. changes of distilled water. Acetic acid was used in the dialysis procedure in order to enhance the separation of T<sub>4</sub> and T<sub>3</sub> from the proteins.

Some material precipitated during dialysis and this material was removed by centrifugation, leaving the water-soluble proteins in the supernatant. The latter was dried by lyophilization. Approximately 1 g of protein was recovered from each 100 g of heart muscle, and up to 10 mg from each pituitary gland.

Before any binding investigation was made, each tissue preparation was tested for the presence of iodine by use of the ceric sulphate-arsenious acid reagent<sup>3</sup>, and was found to be negative. The tissue preparations were checked for contamination with serum proteins by electrophoresis on paper at pH 8.6 in the presence of radioactive T<sub>4</sub>. No radioactivity was found in the inter- $\alpha$  or albumin zone, and this result was interpreted as proof of the absence of serum proteins.

$T_4$  and  $T_3$  binding by human heart muscle, human pituitary tissue, and human serum albumin was measured by peroxidase assay<sup>4</sup>.

Several differences in the binding of thyroid hormones by heart muscle and pituitary tissue were shown. Like human serum albumin (Table 1), a given weight of heart protein (Table 2) had a higher affinity for  $T_4$  than for  $T_3$ . On the other hand, pituitary protein (Table 3) had a higher affinity for  $T_3$  than for  $T_4$ . Since tissue protein preparations were heterogeneous, no comparison of per cent bound hormone per mg of tissue is valid. It is evident, however, that pituitary protein binds no more than 70 per cent of either hormone. Muscle and human serum albumin are similar as to extent of binding of either hormone for higher protein levels.

Human serum albumin is a relatively pure protein, and its association constant and number of binding sites for the thyroid hormone have been evaluated by several investigators. Such information on heart and pituitary protein must await the purification of the binding protein. From the tables it is probably safe to conclude that these tissues differ in their relative affinities for  $T_4$  and  $T_3$  in the present *in vitro* assay system. It cannot yet be stated whether these observations have genuine physiological significance, or merely represent non-specific binding properties of the proteins under investigation.

I thank Dr. George Tritsch, Norma Tritsch and Mr. William R. Rennagel, for their advice and assistance.

## Biological Activity of Degradation Products of Indolepyruvic Acid

Stowe and Thimann<sup>1</sup> reported that they had isolated indolepyruvic acid from maize endosperm by paper chromatography. They used the methods of ammoniacal chromatography. However, Bently<sup>2</sup> found that under these conditions synthetic indolepyruvic acid breaks down into a number of compounds. Moreover, in a recent paper by Kaper and Veldstra<sup>3</sup>, it was shown that both synthetic and isolated indolepyruvic acid break down when chromatographed in a basic solvent. Srivastava<sup>4</sup> has also obtained results similar to that reported by Kaper and Veldstra.

Kaper and Veldstra identified some of the degradation products using chemical and physical methods. The purpose of the work recorded here was to identify the degradation products by the use of biological methods.

The *Avena* first internode assay of Nitsch and Nitsch<sup>5</sup> and the *Avena* curvature assay of Went<sup>6</sup> were used to test the biological activity of the indolepyruvic acid breakdown products. The two tests afore-mentioned were also used for bioassaying the synthetic compounds indoleacetic acid (IAA), indoleglycollic acid (obtained from Prof. A. W. Galston, Yale University) and indolepyruvic acid.

At the beginning of the investigation two spots were thought to be biologically active. However, later experiments showed that if the chromatogram was allowed to develop for about 12 h, only one spot showed biological activity. The active spot on the indolepyruvic acid chromatogram (solvent, isopropanol : ammonia : water, 10 : 1 : 1) corresponded with spot indoleacetic acid in earlier work<sup>3</sup>. A second spot (identified as spot *D* by Kaper and Veldstra) thought to be active was later found to be inactive, owing its activity to the closeness of indoleacetic acid. Standard curves under similar conditions were run for synthetic indoleglycollic acid, indoleacetic acid and indolepyruvic acid using the *Avena* first internode test. The indoleglycollic acid showed no ability to induce growth, whereas indolepyruvic acid and indoleacetic acid did (Table 1). A chromatogram of indolepyruvic acid, developed in an acid solvent (acetic acid : water), was tested with the *Avena* first internode test ( $R_F$  0.17). The activity of indolepyruvic acid is somewhat less than that of indoleacetic acid as stated previously by Went<sup>6</sup>. The results obtained with the *Avena* curvature test were primarily the same as those observed in the *Avena* first internode test (Table 2). Using the *Avena* curvature test, only one spot on the chromatogram promoted curvature, namely, indoleacetic acid. Synthetic indoleglycollic acid did not induce growth. Thus, if the spot thought (by Kaper and Veldstra) to be indoleglycollic acid is that acid, then indeed it would be inactive.

This evidence, together with the earlier physical investigations with paper chromatography and ultra-violet spectrophotometry<sup>7</sup>, suggests that spot *D* is indoleglycollic acid on the basis of its negative biological activity. Excluding indoleacetic acid, the chromatogram contained

## PHYSIOLOGY

### Effect of Thyroid Deficiency in the Ewe on Lamb Viability

THE importance of normal thyroid function in maintaining pregnancy in women has been known for some time, and thyroid medication in some cases of threatened abortion has proved successful<sup>1,2</sup>.

Investigations of the role of the thyroid gland during pregnancy in domestic animals have given conflicting results, the most recent reporting both healthy and weak lambs from thyroidectomized ewes<sup>3</sup>. The ability of thyroid remnants to regenerate into normal active tissue, and also the possibility of supernumerary thyroid tissue, always casts some doubt on the actual total absence of thyroid tissue in surgically thyroidectomized ewes.

In the present investigation, 12 ewes were subjected to a sham operation in which the thyroid was left in place, and a further 12 ewes were thyroidectomized. After oestrous cycles had been recorded in both groups for several months<sup>4</sup>, the ewes were mated and pregnancy was allowed to proceed to parturition. During pregnancy <sup>125</sup>I-uptake was determined to detect any residual thyroid tissue. A month after parturition the thyroidectomized ewes suffered severely during cold weather and 3 died and were examined *post mortem*. Later in the winter of 1962 (southern hemisphere) a further 4 thyroidectomized ewes died of general debility and infection. The remainder were slaughtered and all were thoroughly examined *post*

*mortem*. Only one sham-operated ewe died during this period.

The results of the *post mortem* investigations of thyroid tissue, and the lambing and lamb viability data are given in Table 1.

It is apparent from these results that thyroid deficiency in the ewe has severely reduced both the pre- and post-natal viability of the lambs, despite the presence of an apparently adequate thyroid in the lamb itself;  $0.59 \pm 0.15$  g as compared with  $0.53 \pm 0.19$  g in lambs from sham-operated ewes.

### Evidence that Calcium activates the Contraction of Actomyosin by overcoming Substrate Inhibition

It is believed that muscle contracts or relaxes depending on the concentration of calcium in the sarcoplasm: when the concentration rises to some required level the muscle contracts; when it falls below this level the muscle relaxes<sup>1-4</sup>. The sarcoplasmic reticulum, which can take up calcium actively, seems to play a major part in controlling the level of calcium available to the contractile protein<sup>5-7</sup>.

Actomyosin, isolated from muscle as a gel, retains some of its contractile properties. When exposed to ATP and magnesium the translucent gel shrinks and becomes more dense and opaque—it 'superprecipitates'<sup>8</sup>. Superprecipitation, like muscular contraction, seems to need trace amounts of calcium.

However, the need for calcium in superprecipitation is apparent only at high concentrations of ATP. At low concentrations of ATP, some superprecipitation has been observed even in the presence of ethylene glycol *bis* (2-amino-ethylether)-N,N'-tetraacetic acid (EGTA), which chelates most of the calcium<sup>9,10</sup>. On this basis, Weber and Herz expressed the view that calcium is probably not a direct reactant in superprecipitation<sup>9,10</sup>. Our results support this conclusion, and show that calcium activates superprecipitation at high concentrations of Mg-ATP by inactivating an inhibitory reaction between Mg-ATP and the protein.

Superprecipitation has been measured as a decrease in protein volume, determined after centrifugation. This method is slow and is not able to give continuous measurements of a single fast reaction. A better method measures the process as an increase in optical density<sup>11</sup>. The procedure described briefly in the legend of Fig. 1 and in detail elsewhere<sup>12</sup> is rapid and reproducible; it records automatically and continuously the increase in optical density of an actomyosin suspension.

Calcium had two different effects on superprecipitation, depending on the concentration of ATP. At low concentrations of ATP, calcium decreased the extent of superprecipitation. At high concentrations of ATP, calcium

Table 1. LAMBING DATA FROM THYROIDECTOMIZED AND SHAM-OPERATED EWES

	No. of ewes	No. of lambs	Lambs dead at birth	Lambs dying within one week	Lambs surviving	Average weight of lambs (kg)
Thyroidectomized ewes lacking thyroid tissue	9	6	4	2	—	$2.3 \pm 0.2$ *
Thyroidectomized ewes with regenerated thyroid tissue	3	4	2	—	2	$2.3 \pm 0.4$
Sham-operated ewes	12	8	—	1	7	$2.5 \pm 0.3$

\* Average weight does not include the weights of two prematurely aborted lambs.

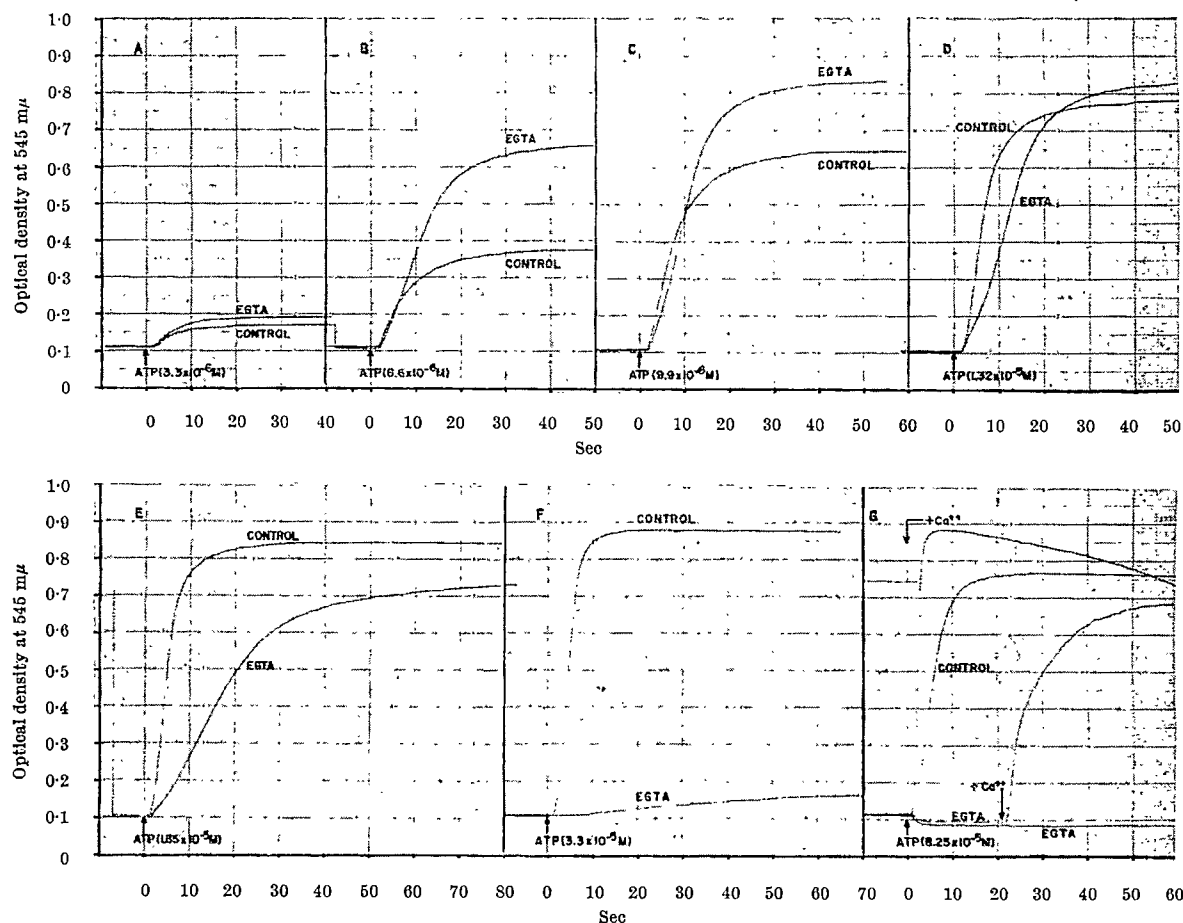

Fig. 1. Effects of ATP concentration on superprecipitation of actomyosin gel with and without EGTA. Twelve ml. of an actomyosin suspension, in the sample cell of a Zeiss spectrophotometer, was stirred continuously by a magnetic bar at the bottom of the cell. Temperature was held constant by circulating water through the cell holder. ATP was added from a microburette through polyethylene tubing. The increase in optical density (2.0 cm light path) that occurred during superprecipitation was recorded continuously on a Photovolt recorder. Conditions: 0.12 mg actomyosin gel per ml.; 0.03 M KCl; 0.005 M MgCl<sub>2</sub>; 0.06 M *tris*, pH 7.4; 25° C. Initial concentrations of ATP are indicated; ATP was hydrolysed while the optical density changed; there was no change without ATP hydrolysis. An optical density of 0.9–1.0 indicates complete superprecipitation. The optical density change stops short of this value when the added ATP is completely hydrolysed. When used, EGTA, 0.002 M in the reaction mixture, was added 30 sec before ATP. CaCl<sub>2</sub>, 0.002 M in the reaction, was added as indicated. Natural actomyosin was extracted from rabbit muscle according to the method of Szent-Györgyi<sup>18</sup>. The gel contained some calcium. All other reagents were treated to remove calcium (for example, with Chelex resin).

increased the extent and rate of superprecipitation. We see these different effects of calcium in the records of Fig. 1. There is normally some calcium in the gel; so the control curves show the response to ATP with calcium; the curves marked EGTA show the response when this calcium is chelated. At low concentrations of ATP, EGTA increased the extent of superprecipitation (Fig. 1, frames A–C). At higher concentrations of ATP the situation was reversed (Fig. 1, frames D–G). Now, with EGTA, the substrate inhibited superprecipitation—the higher the ATP concentration the greater the inhibition. At  $8 \times 10^{-5}$  M ATP (Fig. 1G, bottom curve) there was no superprecipitation at all. As shown on the record, calcium overcame this inhibition immediately and allowed rapid superprecipitation. In the control the calcium was sufficient to allow rapid superprecipitation at high concentrations of ATP; the substrate inhibition that did occur was reversed by adding more calcium (compare the top two curves of Fig. 1G).

The records of Figs. 1 and 2 were obtained at 0.005 M magnesium chloride. When we changed the magnesium concentration we saw two different effects on superprecipitation, again depending on ATP concentration. For example, when the ATP concentration was low, then increasing the level of magnesium increased the rate and extent of superprecipitation. When the ATP concentration was high enough to inhibit superprecipitation (in the absence of calcium) then the addition of more magnesium enhanced this inhibition. Thus, magnesium

appears to act together with ATP in both reactions: that which causes superprecipitation, and that which inhibits superprecipitation in the absence of calcium.

By masking some of the protein SH groups, *p*-chloromercuribenzoate (*p*-CMB) virtually stopped the inhibitory reaction without seriously inhibiting superprecipitation. This selective inactivation of the inhibitory reaction closely resembles the action of calcium; in fact, when the protein was treated with *p*-CMB, calcium was no longer required for superprecipitation at high concentrations of Mg-ATP.

To obtain this effect, we added *p*-CMB (2.0 μmoles per 100 mg of protein) to the reaction mixture 20 sec before addition of ATP. Depending on the concentration of ATP, this treatment had two different effects on superprecipitation with EGTA: (1) high concentrations of ATP, which completely inhibited untreated protein (Fig. 2, curve C), now caused rapid superprecipitation (Fig. 2, curve B)—*p*-CMB blocked the inhibitory reaction; (2) low concentrations of ATP, which did not inhibit untreated protein (Fig. 2, curve D), now caused superprecipitation at a somewhat slower rate (Fig. 2, curve E)—*p*-CMB actually interfered with superprecipitation, but to a relatively small extent.

When the same amount of *p*-CMB was added after ATP it did not substantially reverse substrate inhibition; larger amounts of *p*-CMB, after ATP, did somewhat better, but the effect was limited because these higher levels also seriously inhibit superprecipitation.

Fig. 2. Effects of *p*-CMB on superprecipitation at high and low concentrations of ATP. The conditions of the reaction and the procedure for measuring optical density are given in the legend of Fig. 1. Curves marked *p*-CMB; 2.0  $\mu$ moles of *p*-CMB per 100 mg of actomyosin, added 20 sec before ATP. Curves marked EGTA; 0.002 M EGTA in the reaction mixture, added 30 sec before ATP. Initial ATP concentrations are indicated; ATP concentration changes during the reaction as described in the legend of Fig. 1.

Apparently, ATP protects the protein against certain reactions with *p*-CMB—perhaps by directly masking some SH group(s), perhaps by changing the conformation of the protein—this has been observed before<sup>13-15</sup>.

In all these experiments, we measured ATP hydrolysis during superprecipitation, using the standard Fiske-Subbarow method for determining inorganic phosphate. Without calcium (with EGTA) high concentrations of Mg-ATP inhibited hydrolysis as well as superprecipitation; calcium or *p*-CMB overcame the inhibition of hydrolysis when they overcame the inhibition of superprecipitation. However, calcium or *p*-CMB in the same amounts did not significantly affect hydrolysis at lower concentrations of Mg-ATP.

We conclude that high concentrations of Mg-ATP block superprecipitation and ATP hydrolysis by binding to an inhibitory site on the gel; this site (distinguished from the active site for superprecipitation) can be selectively inactivated by *p*-CMB or Ca. Proteins other than actomyosin may be involved in the inhibition of superprecipitation by Mg-ATP (refs. 16-18); these proteins are probably present in the gel we use, so the inhibitory sites we modify with *p*-CMB may not be on actomyosin molecules, *per se*. In any event, calcium and *p*-CMB appear to inactivate these inhibitory sites without seriously inhibiting the active sites for superprecipitation; thus these agents allow superprecipitation at concentrations of ATP that otherwise inhibit, for example,  $10^{-4}$  M. The concentration of ATP in muscle is probably as high as  $5 \times 10^{-3}$  M (ref. 19)—this is enough to inhibit completely the superprecipitation of actomyosin gel in the absence of calcium; so it seems that calcium may allow contraction in muscle by overcoming substrate inhibition of actomyosin.

It has been known for some time that the ATPase activity of actomyosin can be activated by *p*-CMB (refs. 14, 20); and this activation is seen only at high concentrations of ATP (ref. 20). Moreover, it has been known for a long time that ATP plays a dual part in the actomyosin system: it relaxes (inhibits or clears) at high concentrations and causes contraction (superprecipitation) at low concentrations<sup>8,21</sup>. It has already been reported by Tonomura and Yoshimura<sup>20</sup> and by Murayama and Gergely<sup>15</sup> that *p*-CMB-treated actomyosin superprecipitates at high concentrations of ATP which ordinarily cause clearing. Metal chelators enhance the clearing effect of ATP, and Weber and Herz showed that this is

probably caused by the removal of some calcium from the protein<sup>9,10</sup>.

The data outlined in this communication confirm and extend many reports in the literature. Taken together, we consider that this information forms a cogent argument for the major contention of this communication: that calcium activates contraction of actomyosin by overcoming inhibition caused by high levels of Mg-ATP (refs. 9 and 10), and that *p*-CMB does the same; but neither calcium nor *p*-CMB directly activates the superprecipitation reaction. As shown here, these agents actually inhibit the process; their activating effects are apparent only when the concentration of Mg-ATP is high enough to inhibit seriously actomyosin contraction—and this appears to be the case in muscle.

These results will be reported in detail in a subsequent paper. The work was supported by research grant 6276 and by a research career development award to H. M. L., both from the United States Public Health Service. We thank Mr. Michael Proper for his assistance.

### A Comparison of <sup>3</sup>H- and <sup>14</sup>C-Glucose Metabolism in the Intact Rat

DURING the course of using glucose-6-<sup>3</sup>H in an investigation of glucose turnover in rats, apparent values were obtained for the size of the body glucose pool, the glucose space, and the rates of glucose production and utilization, which were obviously too large when compared to similar work<sup>1,2</sup> using glucose labelled with carbon-14. The possibility was considered that the tritium label on carbon six did not represent the entire glucose molecule, thereby giving inaccurate values for the foregoing parameters of carbohydrate metabolism.

The following experiments were performed in order to ascertain whether or not glucose-6-<sup>3</sup>H represents the entire glucose molecule. Permanent indwelling polyethylene cannulae were inserted into the aorta and vena cava of Sprague-Dawley rats using the method of Popovic *et al.*<sup>3</sup>. Several days later, when the rats had returned to their pre-operative weights, a mixture containing D-glucose-U-<sup>14</sup>C and D-glucose-6-<sup>3</sup>H was administered intra-arterially to the unanaesthetized animals in the post-absorptive state. Serial samples of venous blood were taken at intervals between 30 and 130 min after isotope administration and specific activities of the plasma glucose with respect to both carbon-14 and tritium were determined.

As expected, the specific activities of the plasma glucose decreased with time, presumably because of the

production of new glucose. However, as can be seen in Table 1 under Exp. 1, the  $^3\text{H}$ :carbon-14 isotope ratio did not remain constant but decreased with time, indicating that the tritium was lost more rapidly than the carbon-14. This decreasing ratio provides evidence that the metabolism of the glucose chain cannot be followed quantitatively by a tritium tracer on carbon-6. The mechanisms which could account for this excess loss of tritium include the operation of a tritium isotope effect, cleavage of the carbon chain followed by resynthesis of glucose, or cleavage of the (6)—C—H bond of glucose.

Table 1. THE  $^3\text{H}$ : $^{14}\text{C}$  ISOTOPE RATIOS OF PLASMA GLUCOSE FOLLOWING INTRA-ARTERIAL ADMINISTRATION OF CARBON-14 AND TRITIUM GLUCOSE MIXTURES INTO RATS

Exp.	Isotopic glucose administered	Time after isotope administration	$^3\text{H}$ : $^{14}\text{C}$	Per cent of $^3\text{H}$ lost relative to initial $^3\text{H}$ : $^{14}\text{C}$
1	Glucose-U- $^{14}\text{C}$ and glucose-6- $^3\text{H}$	0	8.3*	
		30	7.5	9.6
		60	6.5	12.2
		90	5.3	36.1
		110	4.2	49.4
2	Glucose-6- $^{14}\text{C}$ and glucose-6- $^3\text{H}$	0	13.9*	
		30	12.3	11.5
		60	11.7	15.8
		110	9.4	32.4
		130	8.4	39.6
3	Glucose-6- $^{14}\text{C}$ and glucose-6- $^3\text{H}$	0	7.5*	
		30	6.6	12.0
		60	6.2	17.3
		90	5.1	32.0
		110	4.7	37.3
		130	4.0	46.7

\* This represents the  $^3\text{H}$ : $^{14}\text{C}$  ratio of the labelled glucose before administration to the rat at time 0.

When tritium is used as a tracer in biological systems, experimental results can be markedly influenced by isotope effects which result in lower reaction rates for tritium transfer as compared to protium. However, our results show that the  $^3\text{H}$ :carbon-14 ratio of plasma glucose decreases with time, giving precisely the opposite result from that which would be expected from a tritium isotope effect<sup>4,5</sup>.

A change in the  $^3\text{H}$ :carbon-14 ratio could result from the formation of new glucose from three-carbon fragments derived from the administered doubly-labelled glucose. It is conceivable that tritium, but not carbon-14, could be lost from these fragments, possibly during the enolization step leading to formation of pyruvic acid. However, von Holt<sup>6</sup> has demonstrated that in non-fasted rats only 12 per cent of the plasma glucose is derived from glucose degradation products in 120 min.

Cleavage of the carbon-tritium bond could occur in an aqueous biological system, either by physical-chemical exchange or by an enzymatic hydrogen transfer system. The former possibility seems unlikely, since we established in the course of this investigation that the tritium label is stable during the synthesis of the glucosatriazole derivative used to isolate the plasma glucose. During preparation of this derivative the tritium-labelled glucose is in an aqueous medium for many hours under varying physical and chemical conditions including high temperatures (110°–140°).

In order to demonstrate that the excess loss of tritium was due to cleavage of a (6)—C—H bond rather than cleavage of the carbon chain itself, glucose labelled with carbon-14 at the sixth carbon was administered together with D-glucose-6- $^3\text{H}$ . As can be seen in Table 1, Expts. 2 and 3, the  $^3\text{H}$ :carbon-14 isotope ratio decreased with time at rates comparable to that of the experiment with D-glucose-U-carbon-14. This strongly suggests that loss of tritium is due to cleavage of the (6)—C—H bond.

One known metabolic reaction that involves cleavage of the (6)—C—H bond is the oxidation of glucose to glucuronic acid. However, the change in the  $^3\text{H}$ : $^{14}\text{C}$  ratio indicates that approximately 40–50 per cent of the glucose pool undergoes hydrogen exchange in 130 min. It is

highly unlikely that such extensive glucuronic acid formation occurs in this time.

The most likely explanation for our results appears to be a hydrogen transfer reaction involving the (6)—C- $^3\text{H}$  bond of glucose. Speculation can be made as to where in the organism such transfer takes place. The fact that the decrease in the  $^3\text{H}$ : $^{14}\text{C}$  ratio is found in the plasma glucose itself tends to rule out the intracellular space of extra hepatic tissues as the site of cleavage. It is well established that in the post-absorptive animal the liver is the source of plasma glucose. Once this plasma glucose enters extra-hepatic tissues, it is phosphorylated and cannot be released as glucose because of the absence of glucose-6-phosphatase in these tissues. However, it is possible that hydrogen exchange at carbon six could occur in the liver. The experiments of Bloom and Foster indicate that tritium is not removed from carbon-6 of intracellular glucose formed from glycerol 3- $^3\text{H}$ , 1,3- $^{14}\text{C}$  in rat liver slices and diaphragm *in vitro*<sup>7</sup>. In both tissues the  $^3\text{H}$ : $^{14}\text{C}$  ratio of glucose isolated from glycogen was equal to that expected from the tritium and carbon-14 content of the precursor glycerol. However, the results do not eliminate the possibility that hydrogen exchange occurs in the process of transfer of the glucose in and/or out of the liver cell. Removal of tritium from carbon-6 could possibly occur at the cell surfaces of other tissues as well.

In conclusion, these results indicate that glucose-6- $^3\text{H}$  cannot be used as a quantitative tracer for the glucose carbon chain in the intact rat. However, the loss of tritium observed in our experiments may reflect an important physiological event in glucose metabolism in the intact organism.

### Sodium-Potassium Ion Exchange Equilibria for Fragmented Human Erythrocyte Ghosts

AN investigation of the calcium-potassium uptake of human erythrocyte ghosts demonstrated that their behaviour was qualitatively the same as a phospholipid-cholesterol membrane model<sup>1</sup>. The membrane model's behaviour can be explained by the presence of negative fixed charge due to a particular phospholipid, phosphatidyl serine<sup>2</sup>. Fragmented human erythrocyte ghosts behave as if they also possess negative fixed charge due to some chemical component or components. The work recorded here extends the analysis of the cation exchange properties of ghost fragments to the equilibrium between sodium and potassium at two concentrations of total salt.

Human erythrocyte ghosts were prepared, treated and analysed as described previously<sup>1</sup>. Some of the material was fragmented by freezing and thawing three times instead of sonication.

Fig. 1. Ion exchange equilibria for fragmented human erythrocyte ghosts in sodium-potassium chloride solutions of various sodium/potassium ratios. Total sodium plus potassium chloride 200 m.equiv./l. Each point represents a single sample.  $\circ$ , K, sonicated;  $\bullet$ , Na, sonicated;  $\Delta$ , K, freeze thawed;  $\blacktriangle$ , Na, freeze thawed

Fig. 2. Ion exchange equilibria for fragmented human erythrocytes ghosts in sodium-potassium chloride solutions of various sodium/potassium ratios. Total sodium plus potassium chloride 20 m.equiv./l. Each point represents a single sample.  $\Delta$ , K, freeze thawed;  $\blacktriangle$ , Na, freeze thawed

Figs. 1 and 2 show the ion exchange equilibria for fragments exposed to sodium and potassium in varying fractions at total concentrations of 200 and 20 m.equiv./l., respectively. If this figure is compared with similar data obtained for the phospholipid-cholesterol membrane model<sup>1</sup>, it can be seen that, again, qualitatively the same behaviour is observed in both systems. One important difference occurs when the results obtained are analysed in terms of estimated fixed charge concentration. (A value of 92 m.equiv./kg  $H_2O$  was obtained from calcium-potassium equilibria in the ghost fragments<sup>1</sup>.) If the ion equilibria is a non-selective Donnan equilibrium, the total ion content of the fragments should be approximately 250 m.equiv./kg  $H_2O$  at the higher total salt concentration

and 96 m.equiv./kg  $H_2O$  at the lower. The observed ion content of the fragments is considerably lower than this, suggesting that the remaining capacity of the fragments is taken up by another cation, probably hydrogen. This is supported by an examination of the binding of monovalent cations to ghost fragments after washing with sucrose solutions<sup>3</sup>. It was found that at least one-third of the total binding capacity was taken up by hydrogen ion at the pH of these experiments (pH 6.0-7.0) and a concentration of total sodium and potassium of 50 m.equiv./l.

The uptake of water by the fragments was independent of the sodium-potassium ratio but depended on the total concentration. In the 200-m.equiv./l. solutions, water uptake was  $7.31 \pm 0.22$  mg  $H_2O$ /mg dry tissue and in the 20-m.equiv./l. solutions water uptake was  $10.98 \pm 0.64$  mg  $H_2O$ /mg dry tissue.

The fragments show no selectivity between sodium and potassium. The results obtained did not depend on the method used for fragmenting the ghosts.

### Mitochondrial Pyridine Nucleotides in the Oxidation of Isocitrate and Malate

CHAPPEL<sup>1,2</sup> has shown that the rate of uptake of oxygen by rat liver mitochondria, with isocitrate in the presence of malate, is greater than the sum of that observed when either substrate is present alone. Since the oxidation of both isocitrate and malate is linked to pyridine nucleotides, the composition of pyridine nucleotides during the oxidation of these substrates was measured.

Fluorescence assays<sup>3</sup> of intact mitochondria<sup>4</sup> demonstrated oxidation of reduced pyridine nucleotides as expected under aerobic conditions (Fig. 1). When ADP was added, the rate of oxidation was markedly enhanced<sup>3</sup>. The addition of malonate (to inhibit malate formation) was without effect on the rate of oxidation of reduced pyridine nucleotides. When isocitrate was added, there was a slight increase in reduction of the pyridine nucleotides which was markedly enhanced on the subsequent addition of malate until a state of anaerobiosis was reached, at which time almost complete reduction of the pyridine nucleotides was observed. Malate, when present without the prior addition of isocitrate, did not change the rate of pyridine nucleotide reduction.

Since fluorescence assays of suspensions of whole mitochondria do not determine which of the pyridine nucleotides is reduced, or whether the increase in fluorescence was due to fluorescence enhancement of bound pyridine nucleotides<sup>5</sup>, the composition of the extractable pyridine nucleotides was determined<sup>6</sup>.

In these experiments, mitochondria (approximately 6 mg protein/ml.)<sup>7</sup> were incubated at 25° C in the isotonic medium described in the legend to Fig. 1, to which 8 mM malonate had been added. The mixture (3.3 ml. in 25-ml. Erlenmeyer flasks open to the atmosphere) was stirred gently. At the end of 1 min 4 mM ADP was added, and at the end of 2 min 1-malate (3 mM) and *DL*-isocitrate (6 mM) were added. At the end of 4 min, acid and alkaline extracts of the pyridine nucleotides were prepared. In control experiments extractions were carried out on fresh

Table 1. MEAN CONCENTRATION OF RAT LIVER PYRIDINE NUCLEOTIDES (nmol/mg protein)

Mitochondrial preparation	NADH	NAD	NADPH	NADP	Total PN
Fresh ( $n=38$ )	$0.76 \pm 0.06$	$1.06 \pm 0.07$	$2.42 \pm 0.15$	$0.11 \pm 0.04$	$4.35 \pm 0.20$
Incubated ( $n=38$ )	$0.39 \pm 0.07$	$2.11 \pm 0.17$	$1.44 \pm 0.11$	$0.26 \pm 0.06$	$4.20 \pm 0.20$
Incubated (with malate) ( $n=10$ )	$0.46 \pm 0.15$	$2.21 \pm 0.14$	$1.03 \pm 0.08$	$0.77 \pm 0.17$	$4.58 \pm 0.26$
Incubated (with malate and isocitrate) ( $n=10$ )	$0.30 \pm 0.06$	$2.20 \pm 0.24$	$1.87 \pm 0.20$	$0.07 \pm 0.04$	$4.43 \pm 0.57$

Means are given with their *S.E.*

mitochondria and on mitochondria incubated for 4 min, in which one or both substrates were omitted. The results are summarized in Table 1.

Under the four conditions shown in Table 1 there was no apparent change in the mean total extractable pyridine nucleotide concentration, suggesting that there was no destruction of pyridine nucleotides. An expected decrease in reduced pyridine nucleotides was observed, however, under all three conditions of incubation, as compared with the fresh mitochondria. Consistent with the fluorimetric tracing there was a marked increase in reduced pyridine nucleotides in the presence of isocitrate and malate compared with that found with malate alone. This was attributable only to NADPH ( $0.84 \mu\text{moles/mg}$  of protein). Since only about one-third of the total pool of extractable NADP was reducible by isocitrate in the presence of malate, this would represent the maximum portion of the pool of mitochondrial NADPH capable of being oxidized by the electron transport chain under the conditions of these experiments.

When mitochondria were incubated with or without added substrate there was a decrease in the concentration of NADPH which was associated with an increase in the concentration of NAD. This could be due to the activity of a phosphatase such as ATPase. Polarographic examination of the mitochondria, carried out on all specimens, however, showed a clear increase in respiratory rate on the addition of ADP, and a return to the previous rate when all the added ADP should have been phosphorylated to ATP. This is evidence against the presence of a very active ATPase. On the other hand, only between 1 and 2  $\mu\text{moles}$  of NADPH/mg of protein were apparently dephosphorylated in our investigations. As the  $K_m$  of ADP for the electron transport chain, under these

conditions, is about  $56 \times 10^{-6} \text{ M}$  (ref. 8), these quantities may have been too small to be detected polarographically as evidence of presumptive ATPase activity.

Experiments in which isocitrate alone was the added substrate consistently showed a loss of about 30 per cent of the total pyridine nucleotides when compared with the unincubated specimen from the same liver, and therefore could not be evaluated.

The rate of NADPH oxidation was accelerated on the addition of malate to the mitochondria, resulting in a relatively high concentration of NADP. This was not seen in the fluorimetric tracing of the mitochondrial suspension. The absence of any significant change in that tracing may have been due to the presence of NADPH not bound to protein, allowing free NADPH to be oxidized by malate or one of its metabolites. This would be in agreement with the suggestion of Klingenberg<sup>9</sup> concerning the ability of malate to facilitate the release of bound pyridine nucleotides through oxidation by oxalacetate.

This work was supported by Research Career Development Award (AM-K3-14,030) and grant AM-07361-1 of the U.S. Public Health Service. We thank Dr. M. Klingenberg for his advice.

### Cytochemical Localization of Ubiquinones in the Retina

A METHOD for the localization of ubiquinones was recently described by Tranzer and Pearse<sup>1</sup>. Subsequent work (to be published) has shown that a positive reaction *in vitro* is given not only by various ubiquinones (UQ 30, 45, 50) but also by members of the tocopherol series ( $\alpha$ ,  $\beta$ ,  $\gamma$ ). Under cytochemical conditions, however, the specificity of the reaction for ubiquinones is much higher and the two groups can usually be distinguished from each other. Vitamin A (alcohol) gives no reaction *in vitro*.

The method has been applied to the predominantly cone retina of the chick (White Sussex) and to the predominantly rod retinae of the albino and hooded rat, and the albino mouse (A strain). In some experiments dark- and light-adapted eyes have been used but the reaction has so far been carried out in the light only. The findings are similar in every case, the state of *in vivo* adaptation of the eye making no appreciable difference.

As shown in Fig. 1, moderate levels of UQ are present in the outer plexiform layer (OP), in the layer of visual

Fig. 1.  $5\mu$  cryostat section of albino rat retina. Shows distribution of ubiquinones in various layers. OP, outer plexiform; RCN, rod and cone nuclei; RCI, inner segment; RCO, outer segment; PE, pigment epithelium. ( $\times 570$ )

cell nuclei (RCN), and in the pigment epithelium (PE). A stronger reaction is present in the inner segments of the photoreceptors (RCI). In all the aforementioned regions the localization of UQ is intramitochondrial. In the outer segments of the photoreceptors (RCO) there is an intensely strong reaction which is necessarily non-mitochondrial. Quantitative investigations have not yet been carried out, but for a given incubation period the reaction in the outer segments is one of the strongest observed in mammalian or avian tissues.

There can be no doubt (from its solubility characteristics) that the UQ of the outer segments is dissolved in the lipid phase of the individual disks composing the outer segment. Their structure has been well described by Sjöstrand<sup>2</sup>. In this position UQ is perfectly situated to act as an electron sink; that is, to receive electrons from systems having a less positive redox potential.

During the period of dark adaptation electrons derived from the regeneration of rhodopsin might be transferred to the UQ of the disks. During either dark or light adaptation the outer segment might receive electrons from metabolic processes carried on by the mitochondria of the inner segment. The photoreceptor, with its disks partly loaded with ubiquinol (reduced UQ), might thus be regarded as a miniature capacitor.

The speculation can be completed by supposing that the stimulus provided by a photon striking and penetrating the outer membrane, and isomerizing a molecule of retinene in one of the disks, sets in motion the flow of electrons and thus an electric current. Since the flow of electrons would be from the outer segment to the inner segment the current would necessarily flow in the opposite direction, that is, into the outer segment. The negative  $\alpha$ -wave of the electroretinogram could be explained on the foregoing hypothesis.

Confirmation of the presence and concentration of UQ in the photoreceptors must be obtained by micro-dissection and micro-assay. If the essential premise outlined here is true, there will be a difference in the state of oxidation of UQ in dark- and light-adapted outer segments. The experiments described here failed to maintain the state of dark adaptation since, after removal of the eyes,

all work was carried out in air, and in the light. Ubiquinol, the reduced form of UQ, is rapidly oxidized by atmospheric oxygen if certain components of the respiratory chain are present (ubiquinol oxidase). If oxidation is prevented ubiquinol will reduce suitable tetrazolium salts directly and dark (anaerobic) incubation of the dark-adapted retina should reveal its presence if the level is sufficiently high. It should therefore be technically possible to make this demonstration and work is proceeding with this in view.

## PHARMACOLOGY

### Neutralization of the Antibacterial Effect of Natural Coumarin Ostruthine by Vitamins K

THE effects of natural coumarin derivatives in the vegetable kingdom are well known, but their effect on micro-organisms has been little investigated up to now. We had earlier found that out of eighteen natural coumarins, for the greater part isolated from the family of *Daucaceae*, only ostruthine (6-geranyl-7-hydroxy-coumarin) caused a marked inhibition of the growth of gram-positive micro-organisms. Related phenolic coumarins, such as umbelliferone (7-hydroxy-coumarin), were ineffective<sup>1</sup>. The effect of ostruthine on the growth of the strain 'BS 270' of *Staphylococcus aureus* was not diminished by the addition of a surplus of glutathione, cysteine, thioglycolate, and 2,3-dimercaptopropanol<sup>2</sup>, that is, substances which possess the ability to react with the lactone ring of the coumarin molecule<sup>3</sup>. Thus, the explanation of the effect of ostruthine can be found in the presence of a side-chain of ten carbon atoms, rather than in the lactone grouping of the molecule.

We have now found it possible to diminish the inhibiting effect of ostruthine on the growth of the strain of *Staphylococcus aureus* 'BS 270' by vitamins K. We tested, on agar plates, with the technique of paper disks<sup>4</sup>, alcoholic solutions of ostruthine alone ( $1 \times 10^{-3}$  M;  $5 \times 10^{-4}$  M;  $2.5 \times 10^{-4}$  M;  $1 \times 10^{-4}$  M), and in a mixture with a double-molar surplus of vitamin K<sub>1</sub> (phylloquinone), vitamin K<sub>2</sub> (farnesyl-quinone), and vitamin K<sub>3</sub> (menadiolone). The effect of ostruthine was not considerably diminished in the mixture of vitamins.

On the other hand, interesting results were obtained in following up the consumption of oxygen in the washed cells of the bacterial culture. Ostruthine causes a strong inhibition of O<sub>2</sub> consumption which cannot be reversed by three-fold washing of the bacterial cells with a buffer solution. The effect of ostruthine alone and of the mixture solutions of vitamins K and other related compounds are given in Table 1.

From Table 1 it is seen that the effect of ostruthine on O<sub>2</sub> consumption can be neutralized by vitamins K<sub>1</sub> and K<sub>2</sub>, and, to a great extent, also by phytol alone.

Table 1. EFFECT OF OSTRUTHINE, VITAMINS K, PHYTOL, AND VITAMIN E ON THE OXYGEN CONSUMPTION IN *Staphylococcus aureus* 'BS 270'

Added Inhibitor	Activator	O <sub>2</sub> consumption as % of control		
		Inhibitor $1 \times 10^{-4}$ M	Activator $1 \times 10^{-4}$ M	Inhibitor + $2 \times 10^{-4}$ M activator
Ostruthine	Vitamin K <sub>1</sub>	20.3	104.2	120.0
Ostruthine	Vitamin K <sub>2</sub>	21.0	98.0	108.0
Ostruthine	Vitamin K <sub>3</sub>	23.7	110.0	21.7
Ostruthine	Phytol	30.8	100.0	82.4
Ostruthine	Vitamin E	22.3	101.6	100.9

The values were obtained by Warburg's method. O<sub>2</sub> consumption in controls = 100 per cent. Standard deviation  $\pm 2.6$  per cent. Main space of vessel in control: final volume 3 ml.; 3.6–4.0 mg dry weight of 18-h-old bacterial culture, 9 mg glucose, 0.05 M KH<sub>2</sub>PO<sub>4</sub>, 0.077 M NaCl, 1.5 per cent ethanol, 0.02 per cent albumin, pH 7.8, temperature 35° C. The bacteria were in contact with the respective substances for about 30 min before the beginning of measurements.

The same ability is also displayed by vitamin E ( $\alpha$ -tocopherol). Vitamin K<sub>1</sub> in a mixture with ostruthine brings about a strong increase in O<sub>2</sub> consumption. Vitamin K<sub>3</sub>, a substance without lipophile side-chain, does not neutralize the effect of ostruthine.

It is scarcely possible to elucidate the mechanism of protective action by the known antagonism of certain coumarins and K vitamins. This mechanism was proved only in coumarins with the hydroxy group on the fourth carbon, such as dicoumarol. Neutralization of the effect of ostruthine by means of the priority bond between the substance examined and the cell is not probable. This is borne out by our finding that the bacterial cells, exposed for 10 min to the effect of vitamin K<sub>1</sub> ( $2 \times 10^{-4}$  M), were, on separation by centrifugation, as sensitive to ostruthine as was the original culture. Similarly, the converse procedure, that is, the action of vitamin K<sub>1</sub> on the cells exposed to the effect of ostruthine, did not lead to any substantial diminution of inhibition. The protective action of vitamin K<sub>1</sub> thus sets in only when both substances are simultaneously added to the bacterial culture.

The explanation seems to be that the ostruthine molecules in the mixed solution with vitamin K<sub>1</sub>, and similarly with other effective substances, are oriented in a manner that renders it impossible for ostruthine with its lipophile chain to combine with the bacterial cells. This interpretation also accounts for the observation that weak neutralization of the effect of ostruthine takes place in the surface tests of alcoholic solutions on agar plates.

I thank Prof. F. Wessely for providing the ostruthine used.

### Identity of Ramycin with Fusidic Acid

RAMYCIN is an antibiotic isolated from the culture broth of a phycomycete, identified as *Mucor ramannianus*. This substance is active against Gram-positive bacteria, mainly *Staphylococci*. Its activity is, however, reduced in the presence of serum, and resistance develops rather quickly *in vitro*. The observation that ramycin prolonged the survival time of mice infected with *Streptococcus pyogenes* and *Staphylococcus aureus*, and was of low toxicity, indicated that this substance should be considered as a potentially useful antibiotic<sup>1</sup>.

Further characterization of the substance was desirable in order to classify it in one of the several groups of antibiotics. Ramycin was described as a colourless substance, containing only C, H and O, with an acid group having a *pK* of 4.6, an equivalent weight of 478 and containing one or more hydroxy groups and double bonds<sup>1</sup>.

Several groups of compounds can be excluded because ramycin contains no nitrogen. Its molecular weight and the fact that it shows only end absorption without characteristic bands in the ultra-violet also eliminate quinones, phenolic substances, and tetrone acids. For this reason, ramycin is likely to be an unsaturated acid of unusual molecular weight or a triterpenoid-steroid-like substance. The biological properties of several products of the last group indicated that it could belong to this class.

Ramycin was compared with several available steroid-like antibiotics. All products were chromatographed in a benzene-formamide system<sup>2</sup>, and the antibiotics were

located on the paper by bioautography on agar seeded with *Staphylococcus aureus*. Ramycin and fusidic acid presented the same *R<sub>F</sub>* value ( $0.30 \pm 0.05$ ), while cephalosporin *P*<sub>1</sub> and helvolic acid were different (*R<sub>F</sub>* relative to *R<sub>F</sub>* of ramycin or fusidic acid =  $1.35 \pm 0.05$  and  $2.6 \pm 0.1$ ). These results were confirmed by thin-layer chromatography on silica gel in the system toluene, acetic acid, and water 5 : 5 : 1 (ref. 3). All antibiotics could be separated by this method, except fusidic acid and ramycin, which had the same *R<sub>F</sub>* value. The colour reagents used for location of the products on the plates were a further aid in identification. All products gave a blue-grey colour after being sprayed with Folin-Ciocalteu reagent, and heated (100°, 10 min). Heating the plates which had been sprayed with antimony trichloride dissolved in chloroform gave different colours: ramycin and fusidic acid, wine red; cephalosporin *P*<sub>1</sub>, green; helvolic acid, no colour. As helvolic acid is less active than the other antibiotics it was necessary to use larger amounts for paper chromatography (3–4 µg instead of 1–2 µg) and thin-layer chromatography (100 µg instead of 50 µg) because helvolic acid gives a weaker colour with Folin reagent. The physical constants published for helvolic acid<sup>4–7</sup> and cephalosporin *P*<sub>1</sub> (refs. 8 and 9) confirm our observations that ramycin is different from these antibiotics. For the same reason, ramycin must be different from polyporenic acid *C*<sub>1</sub> (ref. 10), a product that was not available for direct comparison. The biological data published for ramycin and fusidic acid<sup>11</sup> are identical within the limits of error; some of the physical data (maxima of the infrared spectrum, *pK*) correspond, whereas others ( $[\alpha]_D$ , melting-point) present a small or marked difference<sup>12,13</sup>. For this reason new samples of ramycin were prepared from fresh cultures of *Mucor ramannianus*. These products were identical in all respects with fusidic acid, and were different from dihydrofusidic acid, the physical constants of which are closely related to those of the parent compound<sup>12,14</sup>. The discrepancy between the melting-points of the older and the newer samples can be ascribed to the presence of some impurities in the former (also revealed by thin-layer chromatography). It is also known that the melting-points and analyses of the substances of this group are often perturbed by solvent of crystallization<sup>4,6,9</sup>. We have also observed that the methyl esters of these products, obtained by reaction of the acids with an ethereal solution of diazomethane, could be examined by gas chromatography. The esters of fusidic acid and of ramycin (even the samples which showed the presence of some impurities on thin-layer chromatography) presented the same chromatogram (Table 1). Mass spectrographic investigations were also carried on the methyl esters of both antibiotics at Lilly Research Laboratories. Similar *m/e* peaks of 530 (molecular ion peak), 470, 461 and 452 were obtained in each case.

Table 1. Gas CHROMATOGRAPHY OF METHYL ESTERS OF FUSIDIC ACID AND RAMYCIN\*

Compound	Relative retention time
Cholic acid methyl ester	1.00
Ramycin methyl ester	1.79
Fusidic acid methyl ester	1.79
Dihydrofusidic acid methyl ester	1.64

\* The instrument was an argon chromatograph (Pye Instruments, Cambridge, England) modified to permit the injection of a sample dilution directly on top of the column through a silicone rubber septum. The column wall ahead of the column packing was kept at 300° and the detector cell at 250° by means of separate heating mantles. The column was a 130 cm x 4 mm i.d. glass tubing filled with acid-washed, silanized Gaschrom P<sub>1</sub> 100–120 mesh, coated with 0.75 per cent QF-1, a fluorinated silicone polymer of Dow-Corning Corp<sup>15</sup>.

We may conclude that fusidic acid, a steroid antibiotic with several new characteristics, is produced not only by *Fusidium coccineum*, but also by *Mucor ramannianus* and several cephalosporia<sup>15</sup>.

We thank Dr. E. P. Abraham, Dr. N. Allinger and Dr. W. O. Godtfredsen, for samples of cephalosporin *P*<sub>1</sub>, helvolic acid and fusidic acid; Drs. R. L. Mann and R. T.

Rapala, Lilly Research Laboratories, for the mass spectrographic data and for confirmation of this identification. We also thank Dr. J. Rondelet, E. Evrard and F. Gosselinx for help in the course of this work.

## HAEMATOLOGY

### Electrophoresis of <sup>35</sup>S-labelled Material released from Clumping Platelets

RAT platelets contain a sulphated mucopolysaccharide<sup>1</sup> which, when subjected to paper electrophoresis and to paper chromatography, showed a mobility similar to chondroitin sulphate-A but unlike that of heparin<sup>1,2</sup>. The acid mucopolysaccharide (AMPS) content of human serum increased during the early phase of the blood clotting process<sup>3</sup>; thrombocytes were suggested as a possible source of this additional serum mucopolysaccharide. When thrombin was added *in vitro* to a suspension of <sup>35</sup>S-labelled pig platelets, up to 50 per cent of the radioactivity was lost from the platelets during clumping<sup>4</sup>. Electrophoretic identification of this released material has been attempted in the present investigation.

Platelets of six pigs ( $27.9 \pm 11.1$  kg) were labelled *in vivo* with sulphate-<sup>35</sup>S ( $1.80 \pm 0.18$  mc/kg body-weight) and separated from the blood components as described previously<sup>4,5</sup>. These platelets were resuspended either in a 1:1 or 1:3 mixture of imidazol buffer<sup>6</sup> and 0.85 per cent NaCl or in 0.85 per cent NaCl. Platelet clumping was induced in one-half of each platelet suspension ( $2.49 \times 10^6$  platelets/mm<sup>3</sup>) by the addition of 0.25 ml. 0.025 M CaCl<sub>2</sub> solution and 25 units of bovine thrombin (Parke Davis and Co.) per ml. platelet suspension and incubation at 37° C for 15 min. No calcium or thrombin was added to the other half of the suspension. Both halves of each suspension were centrifuged at 3,000 r.p.m. for 10 min. The platelet residues were digested with 0.5 N NaOH for 18 h at 0° C. Protein was precipitated from the supernatant fluids and from the digested residues with 1.0 ml. 60 per cent perchloric acid per 20 ml. volume and centrifuged at 3,000 r.p.m. for 15 min. Mucopolysaccharides were precipitated with 1.0 ml. 5 per cent phosphotungstic acid in 1 per cent HCl per 10 ml. of the perchloric acid supernatant for 18 h at 0° C. Samples were then centrifuged at 3,000 r.p.m. for 30 min; the precipitate was washed three times with acetone and dissolved in 0.5 ml. 0.1 N NaHCO<sub>3</sub>. Electrophoretic separation was carried out in a Shandon cell<sup>7</sup> using Oxoid strips (Consolidated Laboratories, Inc.). Strips were dried, stained with alcian blue and cut into 1-cm lengths for measurement of <sup>35</sup>S content.

The mean percentage of <sup>35</sup>S-labelled material released on treatment of the platelet suspension with calcium and thrombin was  $47.8 \pm 7.5$ . Phosphotungstic extracts of the supernatant from treated platelets and of both treated and untreated platelet residues characteristically showed three bands (Fig. 1a).

When compared with a control strip (AMPS) containing a mixture of chondroitin sulphate-A, hyaluronic acid and heparin, the mobility of band A was less than that of hyaluronic acid; the mobility of band B was similar to that of chondroitin sulphate. Band C moved further than any of the standard mucopolysaccharides. Extracts of the supernatant from the untreated platelet suspensions showed no stainable material. When standards were run simultaneously with the supernatant from clumping platelets (Fig. 1b), band A again moved less than did hyaluronic acid. Band B and chondroitin sulphate-A appeared to have the same mobility.

The distribution of <sup>35</sup>S on the electrophoretic strips is shown in Table 1 (means from four pigs). The total radioactivity of any strip was taken as 100 per cent and

Fig. 1. Electrophoretic strips of phosphotungstic extracts of platelet supernatants and residues. Bands outlined in lead pencil. *a*, Pre S, supernatant before treatment of platelets with calcium and thrombin; Post S, supernatant after treatment of platelets; Pre P, platelets before treatment; Post P, platelets after treatment; AMPS, mixture of hyaluronic acid, chondroitin sulphate-A and heparin. *b*, Pre S, supernatant before treatment of platelets, with calcium and thrombin; Post S, supernatant from treated platelets, with and without added chondroitin sulphate-A (ChSA), heparin (Hep), or hyaluronic acid (HA).

Table 1. PERCENTAGE DISTRIBUTION OF <sup>35</sup>S ON ELECTROPHORETIC STRIPS

Extracts	Origin	Band A	Band B	Band C
Platelets before clumping	3.3	9.6	86.2	1.0
Platelets after clumping	1.8	9.3	77.7	11.3
Supernatants before clumping	14.3	32.6	56.6	0.0
Supernatants after clumping	1.7	11.1	85.5	1.7

the <sup>35</sup>S content of each band was expressed as a percentage of this total. The two important areas are the B bands from the platelets before clumping and from the supernatant after platelet clumping. Each of these two bands contains approximately 86 per cent of the <sup>35</sup>S-labelled material present on the strips. As band B appears to have the same electrophoretic mobility as chondroitin sulphate-A, and as the major sulphated mucopolysaccharide in rat platelets has been identified as chondroitin sulphate-A<sup>1</sup>, the <sup>35</sup>S released when pig platelets clump in a calcium-thrombin medium is believed to be in the form of chondroitin-<sup>35</sup>SO<sub>4</sub>-A.

## HISTOLOGY

### Demonstration of Neutral Polysaccharides with Fluorescence Microscopy using Acridine Orange

ACRIDINE orange, a basic fluorochrome dye, stains the basophilic constituents of cells, such as nucleic acids (De Bruyn *et al.*<sup>1</sup>, Morthland *et al.*<sup>2</sup>, Armstrong<sup>3</sup>) and acid mucopolysaccharides (Hicks and Matthaei<sup>4</sup>, and Kuyper<sup>5</sup>), but aqueous solutions of this dye do not stain glycogen, paramylum and polysaccharides of the cyst wall of protozoa. All these polysaccharides can be stained with acridine orange after sulphation. Several sulphation techniques have been tried, and the best results have been obtained with chlorosulphonic acid in dry pyridine (Kramer and Windrum<sup>6</sup>). For the sulphation of glycogen 5 min treatment at 65° C is enough, whereas paramylum bodies and cyst wall require 10–15 min treatment at 70°–75° C.

**Procedure.** (1) Make smears of protozoa on clean slides, and dry them in air or fix in Carnoy for 15 min; bring the smears to water; (2) treat with chlorosulphonic acid in dry pyridine at 65°–75° C for 5–15 min; (3) wash in distilled water for 5 min; (4) stain with 0.1 per cent aqueous acridine orange for 5–10 min; (5) wash and mount the smears in distilled water, and seal the coverslip with paraffin; (6) examination of the preparations by ultra-violet fluorescence microscopy using a blue exciting filter (Jena BG 12) and yellow eyepiece filter shows intense red fluorescence of the sulphated polysaccharides.

This treatment with chlorosulphonic acid renders the polysaccharides acidic, with the result that they are able to bind basic fluorochrome acridine orange, and show intense red fluorescence in ultra-violet light. If stained after sulphation with other basic dyes like 0.5 per cent aqueous toluidine blue or 0.01 per cent aqueous azure A, these sulphated polysaccharides show metachromatic staining, which suggests a strongly acidic reaction. They remain negative to periodic acid-Schiff (PAS) stain.

This technique is based on the investigation of glycogen (PAS-positive, salivary amylase labile, non-metachromatic, coupled tetrazolium (CTZ) negative) in the cytoplasm of *Giardia intestinalis*, *Vorticella* sp., *Spirostomum* sp. and *Stylonychia* sp.; of paramylum bodies (PAS-negative, salivary amylase fast, non-metachromatic, CTZ-negative) of *Khawkinia* sp.; and of polysaccharides which in combination with proteins form the cyst-wall (PAS-positive, salivary amylase fast, non-metachromatic, CTZ-positive) of *Giardia intestinalis* and *Stylonychia* sp.

This investigation was carried out in the Laboratory of Parasite Chemotherapy, National Institute of Allergy and Infectious Diseases, National Institutes of Health, U.S. Public Health Service, Columbia, S.C., and supported by an international postdoctoral research fellowship of the National Institutes of Health.

### Thin Sections cut at Temperatures of –70° to –90° C

IN developing a satisfactory system for high-resolution autoradiography of soluble or unbound compounds<sup>1</sup>, we have investigated the possibility of frozen sectioning at low temperatures. At temperatures above –30° C adequate sections can be obtained for certain purposes, but in the temperature range commonly achieved in the standard laboratory cryostat, disruptive crystal formation limits the histological quality, and the thickness of the tissue section limits microscopic and autoradiographic resolution. At –20° C 4μ sections are difficult to prepare and the limit is about 2μ. Optimal conditions for avoiding disruptive ice crystal formation obtain in the range of vitreous ice at temperatures below –130° (refs. 2–4). Above –130° C both cubic and vitreous ice may be converted into the stable hexagonal phase during which the individual crystals can grow to 10μ and cause membrane disruption<sup>5</sup>. The transformation occurs rapidly above –70° C and is pronounced at –60° C. In order to utilize the technique of frozen sectioning for dry high-resolution autoradiography, a method is required which will reduce the risk of ice crystal formation and which will provide thin tissue sections in the range of 0.5μ to 1.0μ or lower.

The cryostat developed and modified for the work described herein (Harris Mfg. Co., Cambridge, Mass., Model 3L-2-075) is designed to maintain temperatures adjustable from –40° C to –85° C ± 1° C. It is equipped with an International Minot Custom Microtome (International Equipment Company, Needham Heights, Mass.) and an ultra-thin-sectioning attachment which is mounted in the freezing compartment (20 in. × 20 in. × 12 in.). A gear-rack adjustment was attached to the knife-holder in order to facilitate fine positioning of the knife. The cryostat is open-topped with an accessory stainless steel removable cover which has a 10 in. × 10 in. access port. The microtome is motor driven or hand operated from outside the cabinet. The open-top cryostat<sup>6</sup> has the advantage of easy access. The temperature may be maintained if excessive air movement is avoided in the cold chamber since air at –85° C has twice the density of air at room temperature. A side opening in the cold chamber permits attachment of a vacuum line for freeze drying within the cryostat. Thus, immediate drying of frozen

specimens without transfer from the cabinet avoids a rise in tissue temperature. The microtome can be lubricated with Molykote Z powder (The Alpha-Molykote Corp., Stamford, Conn.) applied in an absolute alcohol suspension.

The tissue of face area, about 1 mm<sup>2</sup>, is mounted on a specimen holder and quenched in liquid propane at about -180° C. It is then stored in a liquid nitrogen refrigerator. Either a steel or diamond microtome knife is used. Light-weight frozen-sectioning blades should be avoided. We have found that the standard microtome blade is satisfactory for preparing sections as thin as 0.5 µ. We used a knife with a bevel angle of about 30° and a clearance angle of about 25°.

The thickness of the section is mainly determined by the cutting temperature. Temperatures of -20° C are optimal for thick sections (more than 5.0 µ). Temperatures in the range of -70° C to -90° C restrict sectioning to less than 1 µ (liquid nitrogen in the cryostat cabinet lowered the temperature to -90° C). The optimal thickness varies not only with the temperature but also with the type of tissue. At temperatures lower than about -65° C sections thicker than 1 µ could not be cut due to crumbling. However, crumbling is avoided by thinner sectioning. At less than 1 µ rolling up sometimes is prevented by low cutting speeds, about 0.05 to 0.1 r.p.m. The sharpness of the knife and the clearance and bevel angle are very critical at low temperatures. Optimal conditions vary with the knife and the tissue. Sections are prepared under a dissecting microscope with a light beam directed on the cutting edge of the knife. The sections are manipulated and transferred with a fine camel's hair brush. The development of static charge can sometimes be helpful in this tissue transfer. Some loss in the handling of the tissue is to be expected.

A cryostat with variable temperature in the range we have used makes possible sectioning at 1.0 µ and below. Temperature may be the main factor controlling the choice of section thickness, and a cryostat with a range of -10° C to -90° C makes it possible to cut sections with a wide range of thickness. The technique of low-temperature frozen sectioning has been used successfully in the preparation of tissues.

## PATHOLOGY

### 'Immuno-fluorescence' of Mast Cells

A PROPORTION of the mammary tumours induced in rats by oral administration of 9,10-dimethyl-1,2-benzanthracene (DMBA) have been found to undergo spontaneous regression<sup>1</sup>. Attempts to stimulate regressing tumours to grow again by hormonal means have been unsuccessful, and it appears possible that this regression may be due to an immunological mechanism<sup>2</sup>. If this is so it might be possible to demonstrate the presence of anti-tumour antibodies on tumour cells by using Coon's fluorescent antibody technique.

Portions of tumour were removed at biopsy and unfixed frozen sections of these were cut on a cryostat. They

were treated with highly purified rabbit anti-rat globulin which had been conjugated with fluorescein isothiocyanate and were then examined in blue violet light at about 420 mµ using a barrier filter with transmission of more than 450 mµ (lamp filter Chance OB 10 and eyepiece filter Wratten 15 + Chance OY 12).

We were not able to demonstrate the presence of fluorescent antibody on the tumour cells themselves, but large granular cells lying in the stroma of the tumour were found to fluoresce brightly. Further staining of the same sections with toluidine blue enabled us to identify these cells as tissue basophils or mast cells.

This phenomenon was observed in mast cells, both in growing and regressing tumours, in regional lymph nodes, in thymus and in spleen. The test of specificity carried out by attempted blocking with non-fluorescent antiserum was unsuccessful but, on the other hand, mast cells did not become fluorescent when treated with unconjugated fluorescein isothiocyanate as eosinophils did. Similar fluorescent staining of mast cells was observed, however, following treatment of cryostat sections with fluorescein conjugated antiserum bovine albumen. The work was carried out in the main on unfixed freshly frozen cryostat sections of tumour, but the effect was also noted after ethanol and acetone fixation in the cold. It was not observed with living cells suspended in Hanks's solution.

The evidence from our experiments does not favour an immunological explanation for the cause of spontaneous tumour regression; it suggests that the fluorescence we have found in mast cells is non-specific in nature.

### Direct Agar Isolation of Mycoplasmas from Human Leukaemic Bone Marrow

THERE are no reports of the direct isolation of mycoplasmas from human leukaemic blood or blood-forming organs, although the direct isolation of mycoplasmas from the blood of a few septic patients has been claimed<sup>1-4</sup>. In the present investigation, mycoplasmas were isolated from broth cultures seeded with three bone marrow samples obtained on the same day from one of three children suffering from acute lymphoblastic leukaemia (Table 1).

The composition of the broth and agar medium used was that developed in this laboratory and previously used for the isolation of *Mycoplasma pneumoniae*, the aetiological agent of primary atypical pneumonia in man<sup>5-7</sup>.

Bone marrow samples were obtained by aspiration from the iliac crest after the overlying skin had been cleansed thoroughly with iodine and alcohol. The aspirates (0.2 ml.) were mixed directly with 3 ml. of broth containing 1:1,000 thallium acetate and the mixture incubated at 37° C. Although direct streaking of agar medium with the bone marrow specimens failed to yield

\* Isolated from each of 3 specimens collected on the same day.

mycoplasma colonies, mycoplasmas were isolated on agar from three broth cultures seeded with the bone marrow specimens obtained from one patient. The mixtures yielded colonies after incubation for 7 days at 37° C and continued to produce mycoplasma colonies aerobically when streaked on agar and at concentrations of 10<sup>4</sup> colony-forming units per ml. for a period of 90 days. The viability of mycoplasmas in a fluid medium kept for prolonged periods at 37° C is unique and probably distinguishes the strain from others.

Serological investigations were undertaken in an attempt to identify the isolate, called *N-1*, with the known species of mycoplasmas indigenous to man and animals. Growth inhibition tests indicated that *N-1* was not inhibited by antisera against the following species of human mycoplasmas: *M. hominis*, type 1; *M. hominis*, type 2; *M. pneumoniae*; *M. fermentans*; and *M. salivarium*. Growth of *N-1* was also not inhibited by antisera against the animal mycoplasmas, *M. mycoides*; *M. mycoides* var. *capri*; *M. gallisepticum*; *M. gallinarum* and three other strains pathogenic for fowl. The growth inhibition test did indicate that *N-1* is closely related to, or identical with, a new mycoplasma species which was first described in 1961 after isolation from tissue culture samples sent to this Institute for mycoplasma testing<sup>6</sup>. This strain was afterwards determined as belonging to a new mycoplasma serotype<sup>8</sup>. More recently, this serotype has been isolated from the human oral cavity and named *M. orale* by some<sup>9,10</sup> and *M. pharynges* by others<sup>11</sup>. Attempts to isolate *N-1* from the throat of the leukaemia patient were unsuccessful one month after the mycoplasmas were isolated from the bone marrow. Like *M. orale*, *N-1* does not ferment glucose.

*M. orale* probably includes a number of sub-species identifiable by more sensitive tests such as gel-diffusion and complement-fixation. One such sub-species has been reported<sup>12</sup> and, since *N-1* is not inhibited by antisera to this new sub-species, *N-1* may be a second sub-species of *M. orale*.

The successful isolation of mycoplasmas directly from the three samples from only one of the three investigated cases of leukaemia may have been due to the fact that this patient was the most recently diagnosed and was also not treated with drugs before collection of the bone marrow specimens. However, the possibility that *N-1* is a laboratory contaminant cannot be absolutely excluded even though mycoplasmas could not be isolated from: (1) two bone marrow specimens obtained from leukaemia patients receiving chemotherapy; (2) three bone marrow specimens obtained from patients not having malignant disease; (3) throat swabs of persons handling all specimens.

Most of the cytopathic agents isolated recently in tissue cultures exposed to human leukaemic material have been identified as mycoplasmas<sup>13-17</sup>. Furthermore, mycoplasmas have been isolated from tissue cultures inoculated with non-leukaemic human neoplastic tissue<sup>18,19</sup>. Although a few of the species isolated from human malignancies are known human serotypes, a number are clearly unrelated. The Negroni agent<sup>13</sup>, identified as a mycoplasma<sup>14</sup> and isolated from primary tissue cultures inoculated with human leukaemic bone marrow from ten patients, cannot be identified with any known human serotype and is also capable of fermenting glucose<sup>14</sup>. This latter property, in contrast to *N-1*, is shared only with the human mycoplasmas, *M. pneumoniae* and *M. fermentans*.

Because of the high rate of contamination of uninoculated cell lines with mycoplasmas the isolation of mycoplasmas from materials passed through serially passaged tissue cultures is difficult to interpret. This report indicates that mycoplasmas may be present in human leukaemic bone marrow and can be isolated directly in cell-free medium.

Mycoplasmas are the smallest free-living micro-organisms and may share all, or some, of the following properties with viruses: size, filterability, morphology in electron

microscopy, ether sensitivity, ability to haemagglutinate and to cause haemadsorption, interference with virus replication *in vitro*, lack of inhibition by many antibiotics, neutralization by homologous antisera and production of cytopathic effects<sup>6</sup>.

The mycoplasmas are very fastidious in their growth requirements and have metabolic properties which are known to be incompatible with the normal growth of mammalian cells *in vitro*. Most mycoplasma strains convert arginine to ornithine, not by way of arginase, but by a three-enzyme reaction sequence: the arginine dihydrolase system first described in the *Streptococcus*<sup>20,21</sup>. The depletion of arginine from cultures of mammalian cells infected with mycoplasmas results in overt cytopathic effects<sup>22-25</sup>. Interference with the metabolism of mammalian cells by these micro-organisms has also been explained by their possessing a pyrimidine nucleoside phosphorylase capable of cleaving thymidine and other deoxyribonucleosides<sup>16</sup>. Finally, evidence has been obtained indicating that metabolism of amino-acids, other than arginine, is altered in mammalian cells grown *in vitro* and contaminated with mycoplasmas<sup>22</sup>.

These properties make it interesting to speculate on the part which mycoplasmas may play in the aetiology of human leukaemia since presence of the micro-organisms in bone marrow may result in changes in the regulation of myelopoiesis.

This investigation was supported, in part, by research grant CA-04523 and contract PH-43-62-157 from the National Cancer Institute, and by U.S. Public Health Service career development award 5-K3-CA-5838 to one of us (L. H.). We thank Dr. Stanley A. Plotkin for helping us to secure the clinical material used in the investigation, Miss Audrey G. Newnham of the University of Cambridge for the animal mycoplasma antisera, Dr. Norman L. Somerson of the National Institute of Allergy and Infectious Diseases and Dr. Ruth M. Lemcke of the Lister Institute of Preventive Medicine for the antisera to the human mycoplasmas, and Miss Nancy L. Pleibel for her help.

### Pre-erythrocytic Development of *Plasmodium berghei*

THE fate of the sporozoites of *Plasmodium berghei* in rodent hosts has been the subject of much research and speculation and has drawn the attention of malariologists from the early days of the discovery of this parasite<sup>1</sup>. For it was evident to all that this useful and easily accessible *Plasmodium*, an instrument of great promise in biological and medical research, could not achieve or claim true distinction so long as part of its life-cycle remained unmapped and obscure. Early attempts to elucidate the primary development of this parasite were, according to C. G. Huff, unsuccessful (personal communication). Investigations were greatly hampered by the necessity of obtaining sporozoites from wild-caught *Anopheles durenii* from the forest galleries of Katanga and in view of the early inability to infect laboratory-bred anopheline species under experimental conditions<sup>2</sup>. The demonstration early in 1964 of successive cyclical transmissions of *P. berghei* by the bite of experimentally infected *Anopheles quadrimaculatus* in mice, hamsters and tree rats<sup>3</sup> has brought new interest and a renewed attempt to solve the problem of the existence of a primary tissue phase of *P. berghei*. We report here some preliminary results of these investigations and our findings of pre-erythrocytic stages of development of this parasite.

The prepatent periods of 94 sporozoite-induced infections in laboratory-bred animals (white mice, golden hamsters, young albino rats and *Thamnomys*) were investigated. It was found that the incubation period varied greatly. The earliest appearance of parasites in the peripheral blood was observed 65 h after intracardial sporozoite inoculation. The majority of the animals showed a prepatency of 3–6 days. A longer prepatent period of 8–10 days was also observed on several occasions. The investigation brought to light the fact that the route of sporozoite inoculation and the animal-host species had but little effect on the duration of the prepatent period. It was the number of viable, invasive sporozoites introduced by bite or inoculation that was significant. Intracardial inoculation of 360 sporozoites resulted in a patency of 6 days. 37,000 sporozoites from the same course also produced a patency of 6 days. The bite of a single, very lightly infected mosquito which could introduce no more than 30–50 sporozoites produced a parasitaemia in a mouse within 4 days. Sub-inoculation of heparinized blood obtained by cardiopuncture from animals during their prepatent period into clean rodent hosts revealed the existence of a negative, non-infective phase of the blood which lasted from 2 h after sporozoite inoculation to 51 h. This finding is in contrast with the results obtained from blood-induced infections in which an absence of incubation

Fig. 2. Photomicrograph of section of liver (BH 2385) showing mature exo-erythrocytic schizont of *P. berghei* ('Polaroid' camera, oil immersion)

period after massive intraperitoneal trophozoite inoculation has been demonstrated by Schneider<sup>4</sup>.

Fifty-four experimental animals, which were exposed to bites of infected *A. quadrimaculatus* or inoculated with sporozoites, were killed during different stages of their prepatency. Large numbers of touch preparations from the liver, spleen, brain, kidney, bone marrow, lung, mesentery, muscles, heart muscle, adrenal, thymus, skin, intestine and lymph nodes were prepared from each animal. These were fixed in methanol, stained with Giemsa, and examined. Histological sections from the same organs and tissues were also prepared. Tissues were fixed in Carnoy and also in Zenker-formol. They were sectioned at 4  $\mu$  and stained in Giemsa colophonium and in Maximow stain. The present observations relate only to a single animal. The experimental procedure was as follows.

Ninety-one *A. quadrimaculatus* infected with KSP 11 strain of *P. berghei* were allowed to feed on a normal young hamster (BH 2385) on July 22–23, 1964. Fifty-five lightly- and medium-infected salivary glands and 62 heavily-infected crushed midguts were inoculated intramuscularly and intraperitoneally during the same period. The animal was killed at 3 p.m. on July 24, 51.5 h after the first infective bites and 23.5 h after the final sporozoite inoculation. Examination of stained blood smears of the hamster at the time of death did not show any parasites in the peripheral blood. However, two white mice which were inoculated with the heparinized blood obtained by cardiopuncture showed parasites in their blood five days later. A control hamster that was exposed to bites and sporozoite inoculation of the same batch of infected mosquitoes showed parasites in its blood after a five-day prepatency. Examination of touch preparations from the different tissues and organs of the experimental hamster did not reveal forms of parasitic nature. In sections of the liver stained in Giemsa colophonium a few forms were found which show all the morphological particulars of true mammalian plasmodial tissue forms as described in monkey and human malaria. What appeared as a mature schizont in a liver cell was seen through three successive 4  $\mu$  sections. It was 36.5  $\mu$   $\times$  35  $\mu$  and contained approximately 560 nuclei (Figs. 1 and 2). In its appearance the schizont greatly resembled *P. imai* tissue forms as described by Garnham<sup>5</sup>.

The quick development and growth of the pre-erythrocytic stages of *P. berghei* (51 h) are of great interest. It is as yet too early to theorize or to predict if only a single generation of tissue forms develop from the sporozoites or if some schizonts remain in the liver and cause relapses. An intensive search is at present being carried out to find in the material available and in new experimental infec-

## IMMUNOLOGY

### Partial Immunological Restoration of Neonatally Thymectomized Rats with Thymus-containing Diffusion Chambers

SEVERAL investigators have demonstrated the important part of the thymus in the development of immunological competence<sup>1-3</sup>. A point of considerable significance is whether this thymic function is mediated by a cellular or a humoral mechanism. There is both direct and indirect evidence of a humoral factor in thymic activity in the mouse. Thus, genetic studies have established that the cellular constitution of thymus tissue grafted to mice thymectomized at birth is of host rather than donor origin<sup>4,5</sup>, and other work has established that partial immunological restoration of such thymectomized mice can be achieved by thymus-containing diffusion chambers which do not permit the passage of whole cells<sup>6,7</sup>. However, since the restorative effect of such chambers is incomplete, and since thymic extracts have not produced appreciable restoration, it remains unsettled whether a cellular mechanism is involved in addition to the humoral one and investigation in a second species appears to be warranted. The present note reports our investigations over the past 18 months of immunological restoration of neonatally thymectomized rats with thymus-containing diffusion chambers. The results are in general agreement with the mouse experiments, and show that partial immunological restoration is achieved but the restored animals are not immunologically normal.

New-born Sprague-Dawley rats were thymectomized within 24 h of birth by a technique previously described<sup>8</sup>. Diffusion chambers were constructed of TW (pore size 0.45 $\mu$ , thickness 100 $\mu$   $\pm$  10 $\mu$ , nylon reinforced) 'Millipore' filter disks (obtained from the Millipore Filter Corporation, Bedford, Massachusetts) cemented with Millipore No. 1 cement to lucite rings of 13 mm outer diameter, 3 mm height and 1 mm wall thickness<sup>9</sup>. Two different experimental procedures were followed. In the first (Tables 1-4), chambers either empty (thymectomy control) or containing a single whole thymus from 1-3-day-old rats were placed with strictly sterile technique into the abdominal cavity of 11-14-day-old thymectomized animals. Ten days later a second diffusion chamber either empty or containing a 3-7-day-old thymus was similarly placed. Approximately 10 days after the second chamber was inserted, total and differential blood counts on tail vein blood were performed (Table 2) using standard haematological technique. When the animals were 8 weeks old they were immunized<sup>10</sup> in a foot pad with 0.1 ml. of complete Freund's adjuvant containing 0.3 mg of tubercle bacilli and 0.5 mg of bovine serum albumin (BSA). Twenty days after immunization the animals were skin tested with 0.1 ml. of a 1-10 dilution of Old tuberculin

Table 1. MORTALITY \* IN NEONATALLY THYMECTOMIZED RATS

(OT) and 0.1 ml. of BSA (30  $\mu$ g) injected intracutaneously into opposite shaved flanks, and the delayed reaction (average diameter of induration in mm) was measured after 24 h and is recorded in Tables 3 and 4. The skin-grafting experiment (Table 5) was performed differently: the first thymus-containing diffusion chambers were inserted when the animals were 4 weeks old, and the animal was grafted<sup>11</sup> with Sprague-Dawley skin of an unrelated animal of the same sex 3-4 days later. A second chamber was not inserted. The protecting plaster casts were removed 7 days after grafting, exposing conventional full-thickness skin grafts which were examined visually at that time and every 2-3 days thereafter.

While the part of secondary infection in the thymectomy wasting syndrome remains uncertain<sup>1,12,13</sup>, wasting and death are regular consequences of neonatal thymectomy in the rodent. In the present investigation thymus-containing diffusion chambers reduced the excess mortality of neonatally thymectomized rats to approximately half that of animals with empty chambers (Table 1). On post-mortem examination it was found that about half the animals that died had advanced suppurative disease of the lungs, pleura and pericardium, a disease which tends to spread to unthymectomized cage mates, thus accounting for the mortality among unoperated animals. It will be seen in Table 2 that thymus-containing diffusion chambers have only slight restorative value on the depressed lymphocyte counts of neonatally thymectomized rats.

Our results confirm the finding of Waksman *et al.*<sup>2,10</sup> that in the neonatally thymectomized rat delayed hypersensitivity is depressed, and that this depression varies from animal to animal. This variability may be caused by ectopic thymic tissue<sup>14</sup> or may simply be due to the individual variation of a non-inbred species. Nevertheless, in our experiments thymus-containing diffusion chambers do partially restore delayed hypersensitivity to both bovine serum albumin and tuberculin of rats thymectomized neonatally. Thus 13 or 20 restored animals displayed delayed reactions to BSA, whereas only 7 of 16 thymectomized controls with empty chambers reacted. Partial restoration of immunological responsiveness can also be seen in the skin-grafting experiment (Table 5). Only 1 of 12 thymectomized controls rejected skin grafts

in less than 14 days, but 8 of 14 thymectomized animals bearing thymus-containing diffusion chambers had shown rejection at this time. Similar results have been reported in a preliminary communication from another laboratory<sup>15</sup>.

Thus the neonatally thymectomized rat, like the mouse<sup>6,7</sup>, can be partially restored immunologically by thymus-containing diffusion chambers which do not allow the passage of whole cells. However, as in the mouse, this chamber has little influence on the depressed lymphocyte count, and the improvement in mortality, delayed hypersensitivity and homograft reaction is only partial. If anything, restoration is less complete than in the mouse, a fact which may be related to the disadvantage of the larger thymus of the larger animal in diffusion of metabolites and its consequently more limited viability<sup>16</sup>. However, it appears that a humoral mechanism is involved. It remains uncertain whether the incompleteness of restoration of immunological function reflects the inefficiency of the thymus-containing chambers, or implies a second (cellular) mechanism of thymic action.

### Correlation between Complement-fixing Cell Antibody and Immunofluorescent Nuclear Antibody in Hamsters bearing 'SV40'-induced Tumours

THE fact that transformation of hamster cells by 'SV40' results in the synthesis of new viral-induced antigen(s) was first inferred by *in vivo* immunity tests<sup>1-4</sup>. This phenomenon was later detected *in vitro* by complement-fixation<sup>5</sup> and by immunofluorescence<sup>6,7</sup>. This latter approach has characterized the antigen as being particulate, intranuclear and present in 100 per cent of the transformed cells. Corresponding information regarding the intracellular site of the complement-fixing antigen and the proportion of cells in a culture synthesizing it has not yet been reported, and, indeed, such data are difficult to obtain by a direct approach.

Experiments were performed using both the complement-fixation and immunofluorescent techniques in order to correlate the two types of reactions. The sera tested were from tumour-bearing hamsters bled about three months after inoculation with 'SV40'-transformed cells.

Serum dilutions of 1:2 were used in the immunofluorescence assays and 1:10 in the complement-fixation tests. Control sera were obtained from hamsters with tumours induced by the hamster cell line 'BHK21' (ref. 8), which was shown to be free of 'SV40'-tumour cell antigen<sup>9</sup>. Two sources of complement-fixing antigen were used: extracts of 'H-50' and '2X-10' cells. The first is a stable virus-free cell line derived from an 'SV40'-induced hamster tumour<sup>10</sup> and has afterwards undergone 40 passages; the second is also a stable virus-free cell line but derived from hamster cells transformed *in vitro*<sup>11</sup>. Two full units of complement were used, in a semi-micro method to be described. For the immunofluorescence tests the same cell lines were used. They were grown as monolayers on round, 15-mm coverslips and stained with the sera under test as described<sup>11</sup>. Known positive and negative sera were included in each run.

Table 1. COMPARISON OF RESULTS OBTAINED BY COMPLEMENT-FIXATION AND IMMUNOFLUORESCENCE ON SERA FROM TUMOUR-BEARING HAMSTERS

Immunofluorescence	Complement fixation			Totals
	Positive	Questionable	Negative	
Positive	21	1	2	24
Questionable	1	1	2	4
Negative	2	1	28*	31
Totals	24	2	32	58

\* With few exceptions, the negative sera were from animals with small tumours (<10 × 10 mm).

Similar results were obtained in both complement-fixation and immunofluorescence tests with both hamster cell lines. The results of these paired experiments are summarized in Table 1. Of 58 different sera tested, 5 gave questionable reactions in one or the other test. Of the 53 sera yielding clear-cut results in both tests, 49 (93 per cent) gave either positive or negative results both in the complement-fixation and in the immunofluorescence tests. Of these, 21 were positive in both tests and 28 were negative in both tests. The 'BHK21' control sera were uniformly negative against the 'SV40' cell antigens.

From the high degree of correlation between the complement-fixation and immunofluorescence results, both antibodies must develop simultaneously in hamsters carrying the 'SV40' tumours, or the two different methods are detecting the same antibody. If this is true, then the complement-fixing antibody would be the result of the animal's immune response to the particulate, intranuclear, viral-induced antigen present in all virus-free transformed cells. Furthermore, if the antigens detectable by complement-fixation and immunofluorescence elicit the same antibody, then the intracellular site of synthesis of the complement-fixing antigen would also be the nucleus, and the antigen would be produced in every cell of a transformed culture.

### Use of DEAE-'Sephadex' for the Fractionation of Allergic Serum

RECENTLY, Gelotte *et al.*<sup>1</sup> have reported that chromatography on DEAE-'Sephadex A-50' of a 7S fraction of normal human serum resulted in the isolation of IgG ( $\gamma_{ss}$ ) and IgA ( $\gamma_{1A}$ ) components which appeared to be free of other protein constituents. We have modified their procedure for the isolation of fractions containing skin-sensitizing activity from the sera of ragweed-sensitive individuals.

The sera from a treated (B.P.) and untreated (R.A.) allergic patient were used for these investigations and gave essentially identical results. The allergic serum (7 ml.) was dialysed overnight against 0.1 M *tris*-hydrochloric acid buffer, pH 8.0, and filtered on a column (2.5 cm  $\times$  100 cm) of 'Sephadex G-200' (Pharmacia). Elution with the *tris*-hydrochloric acid buffer resulted in 3 peaks corresponding to 19S, 7S and albumin components (Fig. 1). The eluates of appropriate cuts were pooled and the pools concentrated to the initial serum volume (7 ml.) by dialysis against polyethylene glycol M 20. The concentrated fractions were exhaustively dialysed against 0.15 M sodium chloride and analysed for skin-sensitizing activity by the passive transfer (*P-K*) test<sup>2</sup>. As shown in Fig. 1, reaginic activity was localized in 3 fractions (I, II and III) between the descending portion of the 19S peak and the ascending portion of the 7S peak (cf. refs. 3 and 4). A 2-ml. aliquot of 'Sephadex' fraction II, containing the bulk of the skin-sensitizing activity, was dialysed overnight against 0.1 M *tris*-hydrochloric acid buffer, pH 8.0, and chromatographed on a column (1.0 cm  $\times$  26 cm) of DEAE-'Sephadex A-50' (Pharmacia); the resin was previously equilibrated with the same buffer. Two protein fractions were eluted with 0.1 M *tris*-hydrochloric acid and additional fractions after a linear gradient was established from 0.1 to 0.5 M *tris*-

hydrochloric acid of the same pH (Fig. 2). A final fraction was obtained by passing 1.0 M *tris*-hydrochloric acid (pH 8.0) through the column. The cuts for the various fractions shown in Fig. 2 were made according to the shape of the optical density curves. The fractions were concentrated to the initial serum volume (2 ml.) and examined

Fig. 1. Gel filtration of allergic serum (R.A.) on 'Sephadex G-200' in 0.1 M *tris*-hydrochloric acid buffer, pH 8.0, showing distribution of skin-sensitizing antibody. The *P-K* titre of fractions I, II and III are compared to that of the whole allergic serum

Fig. 2. Chromatography of fraction II of serum R.A. on a column of DEAE-'Sephadex A-50'. Elution was started with 0.1 M *tris*-hydrochloric acid, pH 8.0, followed, at the arrow, by a linear gradient of 0.1-0.5 M *tris*-hydrochloric acid, pH 8.0. A final fraction, 11, was obtained by applying 1 M *tris*-hydrochloric acid, pH 8.0, directly to the column. The *P-K* activity of fractions 2, 3 and 4 are compared with that of whole fraction II

Fig. 3. Comparison of immunoelectrophoretic patterns of whole allergic serum (R.A.) and sub-fractions obtained by chromatography of fraction II on DEAE-'Sephadex A-50'. The precipitin arcs were developed with horse anti-serum to whole human serum (left) and with specific goat anti-serum to human IgA (right). S = allergic serum; 1-5 = the various sub-fractions. The precipitin arc obtained with fraction 2 and anti-whole serum appeared as a very faint band in the IgG region and was too weak for reproduction in the photograph

by *P-K* test and by immunoelectrophoresis<sup>5</sup> using specific antisera (Hyland) to human serum proteins (Fig. 3). Fractions 1 and 2 consisted of *IgG* components only: fraction 1 was consistently inactive whereas fraction 2 had slight but definite activity. Fractions 3 and 4 contained the bulk of the skin-sensitizing activity and consisted of *IgA* components. It is noteworthy that the *IgA* components of fractions 3 and 4 had slightly different electrophoretic mobilities.

The chromatographic procedures described appear efficacious for the isolation of discrete serum components with skin-sensitizing activity. Active *IgA* components have been isolated free of other immunoglobulins when tested by immunoelectrophoresis. These findings are in accord with recent investigations<sup>3,4,6</sup> which have indicated the association of skin-sensitizing antibodies with *IgA* components. On the other hand, we have also found an *IgA* component having slight but definite skin-sensitizing activity. Investigations are in progress to determine the presence of trace amounts of *IgA* in this fraction.

The work was supported by grants from the Medical Research Council, Ottawa, Canada, and the Institute of Allergy and Infectious Diseases, U.S. National Institutes of Health.

## BIOLOGY

### Lowering of Immunity in Sheep following Injections of Chlorambucil

THE effects of amino-chlorambucil, an alkylating agent, on the establishment of homografts of haemopoietic tissue in rabbits have been described by Cree<sup>1</sup>. The preliminary experiments described here illustrate the effectiveness of a related compound, chlorambucil, in suppressing certain immunological responses in the sheep.

Preliminary investigations showed that a single intravenous dose of 4 mg/kg body-weight resulted in the death of one sheep from lung oedema in less than 18 h. Post-mortem examination revealed widespread degeneration of

walls of the blood vessels, haemorrhage and extensive necrosis of the kidneys and early necrosis of lymphoid tissue of the spleen, lymph nodes and Peyer's patches. An intravenous dose of 2 mg/kg to an adult Suffolk sheep (85 kg) was, however, well tolerated and produced within 5-6 days a rapid fall in the total circulating leucocyte count from values of about 10,000 to 1,000-3,000 mm<sup>3</sup>. In the absence of further doses of chlorambucil the circulating leucocyte counts rose slowly over a period of weeks to the pre-treatment level. A dose of 2 mg/kg was lethal in two young splenectomized rams.

Four adult Suffolk and one Clun sheep, all of which had been examined regularly over a period of a year by haemagglutination and complement-fixation tests for antibodies against gastro-intestinal nematodes were injected intravenously with chlorambucil (2.0 mg/kg body-weight). Total and differential leucocyte counts were carried out daily.

Intravenous doses of chlorambucil were continued in an attempt to keep the peripheral white cell count at values of approximately 1,000 mm<sup>3</sup>, and at this figure circulating lymphocytes were about 5 per cent of their original values. No ill effects were observed in the sheep. In one animal a single dose of 'Epodyl' (triethylene glycol diglycidyl ether) at the rate of 130 mg/kg body-weight and a single dose of the corticosteroid betamethasone at the rate of 0.24 mg/kg were injected.

Haemagglutination and complement-fixation tests, using an antigen prepared from third-stage infective larvae of *Haemonchus contortus*<sup>2</sup>, were performed at intervals of a few days. In all cases the complement-fixation and haemagglutination titres fell to values of one half or less within 3 weeks of the first injection. The results on two sheep injected with chlorambucil and one injected with chlorambucil and the other drugs are shown in Table 1. The remaining two sheep showed no increase in worm egg counts but antibody-levels fell from titres of 1,280 to 640 and 160 to 80 with the haemagglutination technique and 160 to 40 and 160 to 40 with the complement-fixation technique, respectively.

The post-mortem burden of parasites of sheep No. 66 was as follows:

<i>Ostertagia</i> spp.	1,500
<i>Trichostrongylus axei</i>	400
<i>Bunostomum trigonocephalum</i>	295

Several points of interest arise from these preliminary observations. First, when certain animals are used in homografting experiments it may be necessary to take measures against the parasite burden of the animal as well as taking the usual precautions against bacterial infection.

The rise in egg count which followed the administration of chlorambucil occurred at an interval which was too short to allow for re-infection and, moreover, the animals were housed under worm-free conditions calculated to prevent re-infection. Furthermore, the egg count of ewe No. 66 had been very low or negative for several weeks

Sheep No. 76. Wt., 80 kg; 160 mg chlorambucil injected intravenously on day 1.

Sheep No. 66. Wt., 80 kg; 160 mg chlorambucil injected intravenously on day 1 and 320 mg in divided doses between days 5-20.

Sheep No. 80. Wt., 85 kg; 170 mg chlorambucil injected intravenously on day 1 and 290 mg in divided doses between days 6-15. Day 21. 'Epodyl' intravenous. 11G. 'Betamethasone' intramuscular 20 mg. Day 22. Bone marrow transplant from unrelated sheep.

before the injection of the compound and consequently the parasites must have been dormant or in an arrested stage of development, either as non-gravid adults or possibly as late fourth or young fifth larvae.

Though the phenomenon of arrested development is well known with the *Ostertagia* species, it is interesting to note that it may also occur with hookworms (*Bunostomum*). Other work has verified this. The absence of a substantial rise in egg counts in the other sheep may indicate a fortuitous result with regard to No. 66, but it is felt a more satisfactory explanation might be that they possessed only a small number of parasites. Comparable sheep usually possess low burdens at this time (November).

The haematological effects of chlorambucil in sheep are similar to those observed in the rat by Elson<sup>3</sup> and to those described as occurring in man when the drug is given for the treatment of Hodgkins's disease<sup>4</sup>. The effect of the drug on lymphoid tissue is of special interest since recent investigations have indicated that the lymphoid series along with circulating antibody probably play an important part in the immune response of the host to helminth infection<sup>5</sup>.

These investigations were conducted on sheep exposed to natural gastro-intestinal nematode infection and the burden could not be determined before the injections of chlorambucil were given. With defined experimental infections different types of cytotoxic drugs should be of value in assessing the relative role of the various cell types in immunity to helminths.

Chlorambucil was donated by the Wellcome Foundation.

## Homotransplantation of the Hamster Uterus

THE investigation of utero-ovarian relationships would be facilitated by the development of a successful technique for the transplantation of the uterus. Transplants of the uterus have been examined in several species: in the guinea-pig by Butcher *et al.*<sup>1</sup>, Hechter *et al.*<sup>2</sup>, and Loeb<sup>3</sup>; in the rabbit by Mishell and Motylloff<sup>4</sup>, Chu *et al.*<sup>5</sup>, and Sessums and Murphy<sup>6</sup>; in the mouse by Parfenoff<sup>7</sup> and Hall<sup>8</sup>; and in the dog by Cheval<sup>9</sup>. In these investigations intraperitoneal, intramuscular or subcutaneous sites were used for the transplantation of the entire uterus, uterine slices, endometrium, endometrial scrapings or suspensions of uterine tissue. Histological observations of the transplants either were not always presented or, when reported, usually exhibited degenerative changes. The development of a successful technique for the heterotransplantation of rabbit oviduct to the cheek pouch of the Syrian hamster as reported by McDaniel and Black<sup>10</sup> prompted a similar investigation using uterine transplants. The objective of this investigation was to evaluate the survival of uterine transplants in the cheek pouch of the hamster.

Twenty adult female hamsters (*Mesocricetus auratus*) weighing between 60 and 100 g were used as donor animals. Sub-total hysterectomies were performed on the donor animals anaesthetized with sterile 'Nembutal' (7 mg/100 g of body-weight). Each hysterectomized animal then became a host. The uterus was rinsed in sterile saline and placed in a prophylactic bath consisting of  $5 \times 10^6$  units of buffered penicillin G and 10 g of dihydrostreptomycin sulphate dissolved in 80 ml. of Locke's solution.

After removal of excess connective tissue, the uterus was divided into six segments (each approx. 6 mm long) with both ends of each segment closed with nylon thread ligatures. The segments were then cut from the uterus with a razor blade or fine scissors. The host was then anaesthetized and the cheek pouch everted and washed with 'Zephiran' chloride. Three small slits were cut in the cheek pouch epithelium, and a segment of the uterus was introduced into each one. To prevent loss of the transplants, the incisions were sutured. Afterwards, the transplants were examined at various times with the aid of transilluminated light to determine their condition.

Later (95–132 days after transplantation), the centre transplant from each pouch was removed from five animals. The excised transplants were fixed in 10 per cent neutral formalin, sectioned and stained with haematoxylin and eosin. Histological observations are recorded in Table 1.

Table 1. HISTOLOGICAL APPEARANCE OF THE SURFACE AND GLANDULAR EPITHELIUM OF UTERINE HOMOTRANSPLANTS IN THE HAMSTER

Transplant No.	Days after transplantation	Day of cycle	Surface epithelium	Glandular epithelium
D2 <sub>1</sub>	132	1	+ + + + *	+ +
D2 <sub>2</sub>	132	1	+ + +	+

D8 <sub>2</sub>	95	1	+ + + +	+

\* Relative amounts of epithelial cells.

+ Sparse; + + + +, considerable.

Excised transplants were examined for the condition of endometrial tissue and general histological organization. A lumen of variable size was present in all ten transplants. In any one transplant, the height of the surface epithelium varied from squamous to tall cuboidal or columnar and was intact and healthy in all transplants. Glandular elements with lumina were relatively numerous in five transplants. In the remaining transplants, glands were either sparse or appeared without a lumen. All transplants showed a moderate although variable degree of fibrosis that disrupted the organization of the myometrium and endometrial stroma. Sites of lymphocyte infiltration were infrequent and small. Few plasma cells were seen.

The larger animals weighing 80–100 g were found to be more suitable hosts since their larger cheek pouches more readily accommodated the three transplants. The use of sutures to close the site of transplantation and the use of a prophylactic bath are modifications of the procedure described by McDaniel and Black<sup>10</sup>. These steps prevented the loss of transplants and increased their chance of survival by decreasing the incidence of infection. The most significant result of this investigation is the long-term survival of endometrial tissue in all transplants. The technique described here is at present being used in this laboratory to investigate utero-ovarian relationships in the Syrian hamster.

## Effects of High-power Green Laser Radiation on Cells in Tissue Culture

THE availability of high-power, coherent radiation at new wave-lengths, by means of non-linear optics, has made possible new experiments in the field of radiation effects on cells in tissue culture. It has been shown<sup>1,2</sup> by exposure of melanin granules to ruby radiation at 6943 Å and its harmonic at 3471 Å, that injury sustained by cells in tissue culture is strongly dependent on wave-length. This confirmed the observations by Bessis *et al.*<sup>3</sup> that erythrocytes were destroyed by ruby laser radiation while unstained leucocytes were not affected. Because particular cellular constituents such as pigment granules, haemoglobin and reduced cytochromes *b* and *c* show absorption at 5300 Å, there was great interest in exploring the radiation effects from the second harmonic output at 5300 Å of neodymium (Nd) Q-switched lasers. In the work reported here, a variety of cell types were irradiated with power density at this wave-length in the range of 0.05–100 MW/cm<sup>2</sup> to observe their response.

The experimental arrangement used is shown schematically in Fig. 1. The unfocused 10-MW output from the neodymium laser was passed through a potassium dihydrogen phosphate crystal which was properly index-matched for maximum energy conversion from 1.06 μ to

5300 Å. A dispersive prism separated the 1.06 μ and the green 5300 Å radiation. The green radiation was reflected from a high-quality mirror and focused with an 8-in. lens on the specimen. The power was monitored by measuring the energy incident on a calibrated thermocouple and photomultiplier and by measuring the pulse width by means of an *EG* and *G* travelling wave oscilloscope. The measured pulse width at 5300 Å was 10 nsec and at 1.06 μ it was 15 nsec.

Pigmented retinal epithelium, originating from 12-day chick embryos, provided a suitable cell type containing melanin granules. Figs. 2A and 2B show the destructive effect of 100 MW/cm<sup>2</sup> of the focused green laser energy. Additional experiments indicated that pigmented cells were destroyed at the time of exposure by using power densities of as little as 1 MW/cm<sup>2</sup>.

Having observed previously that the ruby laser produced a slowing of rhythmic muscular contraction<sup>1</sup>, isolated pulsating cardiac muscle cells from a 5-day chick embryo were monitored for changes in their beating rates following exposure to 5300 Å. The response of individual cells showed a wide variation which might have been due, in part, to the location of the specimen within the target area. Two exposures of the cells to 100 MW/cm<sup>2</sup> each produced an average decrease in the beating rate of 45 per cent of the pre-irradiated rate. The morphology of the cells was unchanged.

Acting on the assumption that cytochromes *b* and *c* would absorb sufficient energy at 5300 Å to be modified, the mitochondria of isolated 9-day chick embryo kidney cells were irradiated with a focused laser beam. The morphology of the mitochondria within these tubular epithelial elements was not significantly altered with as many as 20 exposures of 50 MW/cm<sup>2</sup> each, although a transitory beading along the course of the filamentous organelle was observed in some of the cells.

A sheet of chick amnion tissue was mounted in a modified Rose multi-purpose culture chamber and the rate of oxygen consumption measured with a miniaturized Clark electrode<sup>4</sup>. The oxygen was replenished by a

Fig. 1. Schematic diagram of experimental arrangement of Q-switched laser.

Fig. 2A. An image of pigmented retinal epithelial cells from a 12-day chick embryo before irradiation. The dark spheres constitute a cluster of pigment granules which were not spread on the coverslip. The arrow directs attention to a metaphase figure containing pigment granules. B, The same area as shown in A immediately after irradiation with 100 MW/cm<sup>2</sup> at a wave-length of 5300 Å. The cluster of pigment granules and the mitotic figure (arrow) were disrupted. Other elements in the background were injured or killed, depending on the density and number of pigment granules per cell.

Fig. 3. Representative recorder tracings from a physiological gas analyser, depicting oxygen consumption rates by a sheet of chick amnion in tissue culture. Both lines were consecutive recordings from the same tissue. During the second tracing (dashed line), the tissue was exposed three times to MW of power at 5300 Å each (arrows)

medium exchange and a new record was prepared for the same tissue. The amnion was exposed to multiple flashes of an unfocused laser beam during the second record with a total incident power density of 3 MW/cm<sup>2</sup>. Comparing the control and irradiated rates of oxygen consumption, it was observed that respiratory activity was reversibly inhibited for approximately 2 min after the first exposure to the 5300 Å wave-length (Fig. 3).

It was concluded that cells *in vitro* containing pigment granules absorbed the 5300 Å to such an extent that they were destroyed by as little as 1 MW/cm<sup>2</sup>. Muscular contraction was slowed or stopped by an accumulated dose of 200 MW/cm<sup>2</sup> and oxygen consumption was temporarily inhibited following exposure to 3 MW/cm<sup>2</sup>, but the cells survived. Consistent with previous investigations<sup>1,2</sup>, cellular injury produced by the green laser light was considered to be a function of the amount of energy absorbed by specific cellular constituents.

### Angiospermous Hemiparasites

LITTLE research has been conducted into the nutrition of hemiparasitic plants since the early part of this century. These plants, predominantly confined to the sub-family Rhinanthoideae of the Scrophulariaceae, become parasitic by establishing root connexions with the host plant through haustoria.

Koch<sup>1</sup>, Ewart<sup>2</sup>, Kostytschew<sup>3</sup> and Heinricher<sup>4</sup> maintained that the hemiparasites obtain only water and mineral nutrients from a host plant. Bonnier<sup>5</sup> showed

that the hemiparasites have only a weak photosynthetic activity and claimed that these plants are dependent on the host for a supply of assimilates. In 1962, Rogers and Nelson<sup>6</sup>, using radioactive tracer techniques, showed that carbon-containing compounds passed from *Zea mays* hosts to mature plants of the specialized hemiparasite *Striga asiatica*. In the present investigations, using a radioactive tracer technique, it is shown that the hemiparasite *Odontites verna* does receive assimilated carbon-containing compounds from the host plant.

*Striga* and *Odontites* lie at opposite ends of a scale of hemiparasitic specialization, *Odontites* being unspecialized

Fig. 1. Photographs of the treated plant (above) and the autoradiograph (below) showing the movement of labelled carbon from the *Trifolium repens* host to *Odontites*. The arrow indicates the fed leaf

in host requirements and capable of germinating, and completing its life-cycle, with the production of viable seeds, in the absence of a host.

Host plants (*Trifolium repens*) parasitized by individuals of *Odontites verna* were grown in pot culture. Individual leaves of the host were exposed to  $^{14}\text{CO}_2$ , in the light, for 24 h. The pairs of plants were then freeze-dried, mounted and exposed to X-ray plates. Fig. 1 shows one of the resulting autoradiographs demonstrating the presence, in the hemiparasite, of carbon-containing compounds from the host plant. Similar  $^{14}\text{C}$  transfer to the parasite has been observed from gramineous hosts. No transfer occurred when parasite and host were growing together but without haustorial union.

The demonstration that both *Odontites* and *Striga* receive assimilates from a host plant may indicate that this is a general characteristic of the Rhinanthoideae.

### Long-distance Migration of Atlantic Salmon

In recent years a number of authors have reported the recapture in the Greenland area of salmon originally tagged as either smolts or spent fish in British, Canadian and Swedish waters<sup>1</sup>. During the month of October 1964 four salmon originally tagged in rivers in the west of Ireland in County Mayo as clean or spent fish have been reported as having been recaptured off the west coast of Greenland. The details are given in Table 1.

Release data		Table 1		Recapture data	
Date	Place	Date		Date	Place
5/9/63	Carrowmore Lake	6/10/64	Near Julianehaab (60° 40' N, 46° 15' W)		
12/9/63	Carrowmore Lake	21/10/64	Near Supperthoppen (65° 25' N, 53° 00' W)		
25/3/64	Burrishoole River	18/10/64	Off Kangamiut (65° 49' N, 53° 19' W)		
25/4/64	Burrishoole River	17/10/64	Off Kangamiut (65° 49' N, 53° 19' W)		

The first two fish were tagged by an official of the Fisheries Division of the Department of Lands, Dublin, and the second by officials of the Salmon Research Trust of Ireland, Inc., sponsored by Arthur Guinness, Son and Co., Ltd., and the Minister for Lands for Ireland.

### MICROBIOLOGY

#### Effect of pH and Temperature on Structural Integrity of an L Form of *Streptococcus pyogenes*

L FORMS obtained from group A *Streptococci* are osmotically fragile. Suspensions of the L form, which lacks the rigid bacterial cell wall, in osmotically unprotective environments results in structural disintegration

and loss of viability<sup>1</sup>. A paucity prevails in the literature, however, concerning the effect of temperature and pH on the integrity of the L form in its protective growth medium. This communication deals with a comparison of the effect of such alterations of the growth environment on the structural stability of a group A  $\beta$ -haemolytic *Streptococcus* and a derived stable L form obtained from it with the aid of penicillin.

The *Streptococcus* and L form are the same as those used earlier<sup>2</sup>. The medium for each of these organisms was described<sup>3</sup>. Sterilization of all media by either heat or filtration afforded identical results. For these investigations, 50 ml. of media in 125 ml. Erlenmeyer flasks equipped with side-arm tubes were inoculated with 0.5 and 1.0 ml. of overnight cultures of the coccus and L form, respectively. All incubations ( $\pm 0.25^\circ\text{C}$ ) were performed in a thermostatically controlled water bath. Each organism was grown at  $37^\circ\text{C}$  until an optical density of between 0.250–0.300 (approximately mid-logarithmic growth) was attained before adjusting cultures to the experimental pH with small volumes of either concentrated sodium hydroxide or hydrochloric acid. Cultures were transferred to water baths adjusted to the desired temperature and lysis followed spectrophotometrically; growth and lysis being determined at frequent intervals with a Coleman model 14 spectrophotometer at 650 m $\mu$ . The temperatures and pH's examined are indicated in one of the figures. Un-inoculated media served as blanks for growth; pH-adjusted aliquots of the supernate of collected cultures served as blanks for the lysis investigation. Each value is an average of two determinations. Only logarithmic cocal and L form cultures, the growth rates of which (doublings/h) at  $37^\circ\text{C}$  were close to 1.1 and 0.7 respectively, were used. The rate of L-form lysis is expressed as the negative slope of a culture that had undergone at least 50 per cent lysis within 50 min.

Fig. 1 illustrates a typical example of the effect of an increase in pH on the structure of logarithmically growing cocal cells before and after cell wall removal (that is, stable L form). Fig. 2 summarizes the results of temperature and pH alterations of the growth medium on structural stability. As is apparent, L form structural disintegration was most pronounced at  $48^\circ\text{C}$ , with maximum destruction of cell structure occurring in combination with a pH of 9 (Fig. 2). The decrease in turbidity was correlated with L form structural disintegration by dark phase-

Fig. 1. Effect of pH increase on structural stability of the coccus and derived L form. Arrows indicate time each culture was adjusted to pH 9 and reincubated at the growth temperature ( $34^\circ\text{C}$ ). Growth and lysis rates determined from the straight line portion of curves after pH and temperature changes.

Fig. 2. Summary of results of temperature and pH changes of growth medium on structural stability. Hatched, *Streptococcus*; stippled, *L* form.

contrast microscopy. Microscopic examination of the coccus failed to reveal similar pronounced morphological alterations following identical treatment. Under these conditions of investigation, pH 7 was found to afford the greatest stability to *L* form structure within the wide limits of temperature and pH examined. The effect of alkalinity on *L* form structure increased with increasing temperature; pH 5 exerted its maximal detrimental effects only at 48° C. Following lysis of the *L* form at pH 5 at temperatures of 26° and 34° C, a slow but constant increase in turbidity over an additional 100 min re-occurred. This new growth proceeded at 0.11 and 0.25 doublings/h at 26° and 34° C, respectively. Growth was ascertained by phase microscopy which revealed the reappearance of the typical *L* form structure. Similar results were not noted at the other pH's and temperature examined.

These results suggest that the unprotected membrane of the *L* form is initially affected by drastic changes of pH and temperature on the growth medium. These alterations have provided an insight into the structural instability of the *L* form. Since the *L* form mimics the acidity production of the parent coccus, controlled pH and temperature of the growth medium appears necessary in order to prevent harmful effects on *L* form structure during growth. Coupled with the great diversity of individual cell sizes observed during *L* form growth<sup>4</sup>, these findings may also prove useful in further investigations of *L* form viability and physiology.

## ENTOMOLOGY

### Sex Attraction in *Rhopaea* (Coleoptera : Scarabaeidae)

THE presence of sex pheromones in insects has been well documented<sup>1</sup>. Travis<sup>2</sup> and Jeannel<sup>3</sup> reported a natural sex lure in the scarab beetles *Lachnosterna lanceolata* Say and *Pachypus cornutus* Olivier respectively, and our investigations with *Rhopaea* spp. provide another such record for the Scarabaeidae.

The *Rhopaea* group of pasture cockchafers are believed to be of considerable economic importance in some areas in

Australia. It was therefore of great interest when a sex attractant was first indicated by large numbers of male *Rhopaea magnicornis* Blackburn trying to dig their way into a field cage containing a virgin female of the same species. Although several species of *Rhopaea* may exist together in mixed populations the sex attractants appear to be species-specific.

It was later found that the scent left in cups which had housed 4- to 15-day-old virgin *R. magnicornis* females was alone capable of eliciting the typical graded male response of fanning out the lamellae of the antennal club and excited walking, culminating in rapid fluttering of the wings and searching behaviour.

Marked *R. magnicornis* males were used in release and recapture trials to determine distances over which caged females could attract males. Field tests were conducted during the first 1-2 h after sundown when the beetles were very active. Recoveries of marked males were affected by wind speed. If breezes were unsteady or less than 3 m.p.h. the males flew at random in search of females; but in steady breezes of about 5-7 m.p.h. the males flew upwind to females. Thus, within 15 min marked males released downwind from the centre of a line of caged females placed at right angles to the wind direction were attracted to virgin females caged up to 30 yd. away. Presumably, competition of wild field females prevented recapture of marked males beyond 30 yd.

In the laboratory *R. magnicornis* females took from 3-8 days to reach the surface of the soil after emerging from their pupal cases and could produce an attractant by the third day of adult life.

Under favourable conditions a caged virgin *R. verreauxi* Blanchard female could attract as many as 50 males within a few minutes. Virgin females of *Rhopaea morbillosa* Blackburn and *R. verreauxi* were capable of emitting their respective attractants on at least three successive nights and, presumably, until a successful mating is achieved. However, in Nature, mating probably takes place soon after a female begins producing an attractant because the multiple-mating habits of males make available a large number of males.

Apparently, no attractant is produced after mating occurs. When caged virgin females were allowed to mate, males which had clustered outside the cage departed within a minute.

The attractant is emitted from the abdomen of the female. Five males were attracted to the abdomen of a dissected *R. magnicornis* female, after which one male was allowed to copulate with it. No males were attracted to the head or thorax.

*Rhopaea* females are capable of flight, unlike the short-winged females of *Lachnosterna lanceolata*<sup>4</sup> and the wingless females of *Pachypus cornutus*. However, females of some *Rhopaea* spp. are seldom seen in Nature, although those of *R. verreauxi* are known to make short dispersal flights after emerging from the ground at dusk.

*R. verreauxi* females were often observed resting or mating on the leaves of *Eucalyptus pauciflora* Sieber ex Spreng, a habit unknown for other species in the genus. Females of *R. heterodactyla soror* Blackburn and *R. magnicornis* have been observed only on tufts of grass or on the ground.

The adults of many scarab species in Australia are attracted to a common food source, such as *Eucalyptus* trees, where they feed and mate; such species have less need to rely on sex pheromones to bring the sexes together and are not known to produce them. On the other hand, adults of the North American scarab, *Lachnosterna lanceolata*, feed on a variety of plants, for example, alfalfa, clover, collards, wheat and oats<sup>5</sup>, and a sex pheromone is presumably of great selective advantage as a mechanism for uniting the sexes. The species of *Rhopaea* investigated are not known to feed as adults, and have only a rudimentary digestive tract. The females release

a potent chemical which attracts the males of the same species. *R. verreauxi*, the only species which has been found on trees, has the best-developed (but non-functional) digestive system; this leads us to suggest that the change in adult feeding habits in this species may have occurred more recently than in the others.

## GENETICS

### Sex Ratio in Laboratory Populations of *Drosophila*

LABORATORY populations of *Drosophila* have been widely investigated in recent years, and extensive data are available for changes in the frequencies of alternative genes or chromosomal rearrangements. However, little attention has been given to changes in the sex ratio in such populations.

Twelve populations of *Drosophila melanogaster* were examined in this laboratory, using a modification of the cage designed by Thomson<sup>1</sup>. Each population was derived from an inbred line maintained by single sib matings for 14–19 generations.

From each cage a random sample of 300 adult flies was taken periodically to follow changes in the frequency of two segregating sex-linked allelic mutants (white and apricot eye, or white and blood eye), and the proportion of males was also determined.

In 80 of the 229 samples the proportion of males was significantly different from 0.5. There were more significant excesses of males than females, 58–22. For individual cages, the results varied from one significant sex ratio in 21 samples to 18 significant sex ratios in 22 samples. The results for two of the populations are illustrated in Fig. 1, where the proportions of males differing significantly from 0.5 are indicated by small circles.

Heterogeneity of the sex ratio was tested for each population using the Brandt and Snedecor  $\chi^2$  test. In all cases a significant  $\chi^2$  was obtained, the probability of the  $\chi^2$  being 1–2 per cent for two populations and  $P < 0.001$  for all other populations. There seemed to be no association between significant departures from a 1:1 sex ratio and either gene frequency or population size,

and in consequence it is suggested that this variability in sex ratio should not be limited to populations segregating for these sex-linked mutants.

Most of the published accounts of either large or small laboratory populations record changes in frequency of autosomally inherited characters, and do not present the results separately for the two sexes. Frydenberg<sup>2</sup> reported the sex ratio in a number of populations of *Drosophila melanogaster* of average size 550. 50 per cent of these showed significant departures from  $r = 0.5$ , but, as each population was only sampled once, no information is available on variability with time of these sex ratios. A number of investigations of populations with segregating sex-linked genes have reported variable sex ratios, but these have mainly been detected in small populations<sup>3</sup> where chance effects might be expected to contribute largely to the extreme sex ratios obtained. Thomson<sup>4</sup> reported variable sex ratios in large laboratory populations of *Drosophila melanogaster* segregating for sex-linked alleles at the white eye locus. He stated that the excess of one or other sex appeared to be an intrinsic character of each population, but did not indicate whether or not there was heterogeneity of the sex ratio with time.

Thomson's populations were similar to those examined in this laboratory in that each was homogeneous at all loci except perhaps for those closely linked to the white-eyed locus. It is possible that such populations are extremely sensitive to small unavoidable environmental fluctuations, leading to an instability of the sex ratio which would not be observed in a genetically less homogeneous population. This suggestion is now being examined by comparing the variability of the sex ratio in populations of *Drosophila melanogaster* derived directly from laboratory stock bottles with that in populations originating from the same stocks but made homogeneous at all loci. Both wild-type populations and populations homozygous for an autosomal or sex-linked mutant are being considered.

### Difference in the Behaviour of Eu- and Hetero-chromatin: Crossing-over

THE recombination map-length (0.04 per cent) for the heterochromatin of the X chromosome of *Drosophila melanogaster* is far less than would be anticipated from its mitotic bulk (half the chromosome at metaphase) and considerably less than would be estimated from its polytene-length (17 bands of 1,024)<sup>1</sup>. An exchange frequency comparable to the euchromatic average for the 66 map units of the X chromosome should result in a heterochromatic map-length of at least 1.6 per cent and possibly as high as 33 per cent, depending on which cytological measurement more closely approximates the actual physical length of X heterochromatin. In order to decide whether this low frequency of crossing-over reflects a basic difference in the exchange behaviour of eu- and hetero-chromatin rather than an over-estimate of the physical length of X heterochromatin, use was made of the ability of autosomal inversions to increase crossing over on the X chromosome, the interchromosomal effect on recombination.

The region between suppressor of forked (*su-f*, 66.0) and non-yellow *Dp(scV1y+)* located on the short right arm of the X includes most of the X heterochromatin while the carnation (*car*, 62.5) to *su-f* region includes the euchromatic heterochromatic junction and adjacent euchromatin for comparison. Sisters of the genotype

Fig. 1. The proportion of males plotted against time for two of the populations. Readings differing significantly from 0.5 are indicated by small circles.

*y f car su-f/y f. Dp(sc<sup>V1</sup>y<sup>+</sup>)* with or without the autosomal inversions, SMI and Ubx<sup>130</sup>, were crossed to *y f car su-f/Y* males and the *F*<sub>1</sub> scored for recombination.

It can be seen from Table 1 that the *car-su-f* region which includes euchromatin exhibits a pronounced increase in recombination in the presence of the autosomal inversions while the region which is heterochromatic is refractory to the interchromosomal effect. The interchromosomal effect on recombination which has hitherto been described as most pronounced in 'heterochromatic regions' is more accurately described as pronounced in the proximal euchromatin but absent in heterochromatin.

Table 1. RECOMBINATION IN EU- AND HETERO-CHROMATIN OF THE X CHROMOSOME

Autosomal inversions present	No. of flies scored	Per cent recombination Euchromatic <i>car-su-f</i>	Heterochromatic <i>su-f-y<sup>+</sup></i>
None	5,005	3.54	0.04
SMI; Ubx <sup>130</sup>	9,278	9.07	0.04

Crossing-over apparently occurs in the early growth stages of the oocyte<sup>3</sup>. In spite of the generally unfavourable nature of the cytological material, heterochromatin is demonstrable in the oocyte nucleus throughout these early growth stages. Moreover, the nucleolus organizer is in X heterochromatin, and when the nucleolus is first visible (stage 3) and in succeeding stages it is seen to be associated with heterochromatin<sup>3</sup>. It has recently been demonstrated that condensed, pycnotic chromatin is relatively inactive in the synthesis of RNA compared with the more diffuse chromatin<sup>4</sup>. The results recorded here make it possible to correlate another aspect of chromosome behaviour with a particular cytological state and indicate a fundamental difference in the exchange behaviour of eu- and hetero-chromatin owing, apparently, to the condensed state of heterochromatin at the time of exchange. It follows that the more diffuse chromatin condition is a prerequisite for the regular and frequent exchanges that occur during meiosis.

This work was sponsored by the U.S. Atomic Energy Commission under contract with the Union Carbide Corporation.

### Pseudocholinesterase Variants in Japan

SINCE Kalow<sup>1</sup> in 1956 demonstrated a genetically controlled atypical (dibucaine resistant) variant of human pseudocholinesterase (acylcholine acylhydrolase [Enzyme Commission: 3.1.1.8]) much information has been gained on the polymorphism of this enzyme, an esterase of the serum of which the function is not known. Besides the most common gene (*Ch<sub>1</sub>U*) responsible for the synthesis of the usual pseudocholinesterase at least three other genes have been described on the same autosomal locus, namely, the alleles *Ch<sub>1</sub>D*, *Ch<sub>1</sub>F* and *Ch<sub>1</sub>S*, each producing variant enzymes different from the normal pseudocholinesterase. There is no difference in health between various genotypes of the usual gene *Ch<sub>1</sub>U* and those of the alleles *Ch<sub>1</sub>D*, *Ch<sub>1</sub>F* and *Ch<sub>1</sub>S*, unless either homozygotes or heterozygotes of each of the latter three genes are subjected to the application of the muscle relaxant succinylcholine (succinylidicholin) when an abnormally prolonged apnoea is observed. Heterozygotes with both a variant gene and the usual gene do not show this sensitivity.

Various methods have been developed to identify the different types of the enzyme in the homozygotes as well

as in the heterozygotes. Among the inhibition-tests the most common are those using dibucaine<sup>2</sup> or NaF<sup>3</sup> as inhibitors.

The incidence of the heterozygotes for the atypical allele *Ch<sub>1</sub>D* in Europe and Canada seems to be almost constant among various populations so far investigated: about 3-4 per cent<sup>4-7</sup>. Recent investigations on 433 Israelites suggests a higher frequency of the gene *Ch<sub>1</sub>D* (6.3 per cent) among them<sup>8</sup>. Australian Aborigines and Malaysians are said to show no significant difference from the European populations<sup>9,10</sup>. Consequently the atypical type (*Ch<sub>1</sub>D*) of pseudocholinesterase is believed to have a remarkable uniformity of incidence in widely different populations, suggesting that there are (or have been) differences between the selective values of pseudocholinesterase-variants of the various populations<sup>10-12</sup>. Investigations on the incidence of the gene *Ch<sub>1</sub>F* (fluoride resistant) suggests it has about the same frequency as that of the gene *Ch<sub>1</sub>D* (refs. 7, 12). Homozygotes for the 'silent gene' *Ch<sub>1</sub>S* are supposed to be found one in 100,000 (ref. 11). We have recently investigated 100 serum samples from Japan, randomly collected in Tokyo from healthy blood donors. The whole material was investigated at first by two screening tests, the diffusion-test<sup>13,14</sup> and the inhibition-test with RO2-0683 as inhibitor according to Kalow<sup>15</sup>. The dibucaine and fluoride numbers were measured afterwards on each of the 100 sera. Neither heterozygotes nor homozygotes for the gene *Ch<sub>1</sub>D* were found by the four methods described, while two sera were found to be heterozygous for the gene *Ch<sub>1</sub>F*.

The esterase level in our material was found to be lower than that of other populations. We do not believe that the depressed enzyme activity can be explained by a five days' transport from Japan to our laboratory at uncontrolled temperature, but further investigations will be necessary. Both the dibucaine and the fluoride numbers showed normal values.

The foregoing result was confirmed by the screening tests<sup>13-15</sup> on a further 150 Japanese sera, in which no *Ch<sub>1</sub>D* phenotype was found. The frequency of the heterozygotes for *Ch<sub>1</sub>F*, on the other hand, seemed to be about the same as found in the earlier investigation. This may suggest that the incidence of the gene *Ch<sub>1</sub>D* is not as evenly distributed as was assumed from earlier investigations.

This work was supported by the Alexander von Humboldt-Stiftung, the Deutsche Forschungsgemeinschaft and the Bundesministerium für Wissenschaftliche Forschung, Bad Godesberg.

We thank Dr. H. Sakura, Department of Legal Medicine, Medical Dental University, Tokyo, for sending us the sera.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, February 15

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 3 p.m.—Colloquium on "Design of Solid State Power Supplies".

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE (in the Council Room of the Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—Mr. R. M. Young: "Mind, Brain, and Behaviour: Gall to Ferrier".

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. A. J. Clarke: "Hatching Agents for Cyst-Forming Nematodes".

## Tuesday, February 16

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP (joint meeting with the Agriculture Group, at 14 Belgrave Square, London, S.W.1), at 10.30 a.m.—Meeting on "Potatoes".

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. H. J. Ralston: "National Parks of the Western United States".\*

UNIVERSITY OF LONDON (at the London School of Economics, Houghton Street, London, W.C.2), at 5 p.m.—Dr. J. H. M. Beattie: "Ritual and Social Change".\*

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—Sir Alfred Sims: "Warship Design: Interdependence of Science and Engineering" (James Forrest Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Universities Under Fire" opened by Prof. W. E. J. Farvis.

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Prof. R. L. F. Boyd: "The Moon". (Afternoon lecture for Sixth Form Boys and Girls in Schools from London and the Home Counties. To be repeated on February 17, 23 and 24.)

UNIVERSITY OF LONDON (at the Imperial College of Science and Technology, London, S.W.7), at 5.30 p.m.—Prof. E. R. Laithwaite: "Propulsion Without Wheels" (Inaugural Lecture).\*

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. K. B. Roberts: "Peripheral Blood Lymphocytes". (Tenth of sixteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).\*

INSTITUTION OF MECHANICAL ENGINEERS, NUCLEAR ENERGY GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Achievement of Availability in Gas-Cooled Reactors".

PLASTICS INSTITUTE, LONDON SECTION ENGINEERING SUB-GROUP (at "The Coachmakers Arms", 88 Marylebone Lane, London, W.1), at 6.30 p.m.—Meeting on "Compression Moulding".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the Kingston College of Technology Chemical Society, at Kingston College of Technology, Penrhyn Road, Kingston, Surrey), at 7 p.m.—Prof. S. F. Mason: "Circular Dichroism".

## Wednesday, February 17

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 2 p.m.—Dr. A. A. Sharp: "Defibrination Syndrome".\*

ROYAL SOCIETY OF MEDICINE, COMPARATIVE MEDICINE SECTION (at 1 Wimpole Street, London, W.1), at 5 p.m.—Meeting on "Electroencephalography in Animals".

INSTITUTION OF ELECTRICAL ENGINEERS (at the Central Hall, Westminster, London, S.W.1), at 5.30 p.m.—Mr. F. C. McLean, C.B.E.: "Colour Television" (Faraday Lecture).

UNIVERSITY OF LONDON (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. F. R. Whatley: "Botany Revisited" (Inaugural Lecture).\*

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, RADAR GROUP (at 9 Bedford Square, London, W.C.1), at 6 p.m.—Mr. R. Aste: "Transistorized Equipment Designed for Television Exploitation of Radar Information".

INSTITUTION OF MECHANICAL ENGINEERS, INDUSTRIAL ADMINISTRATION AND ENGINEERING PRODUCTION GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Trends in Casting Versus Welding".

SOCIETY OF ENVIRONMENTAL ENGINEERS (in the Mechanical Engineering Department, Imperial College of Science and Technology, London, S.W.7), at 6 p.m.—Mr. Trevor Owen: "A Criticism of the Contemporary Approach to Environmental Engineering".

OIL AND COLOUR CHEMISTS' ASSOCIATION, LONDON SECTION (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. G. L. Holbrow: "Dirt Pick-Up of Paints".

ROYAL AERONAUTICAL SOCIETY, GRADUATES' AND STUDENTS' SECTION (at 4 Hamilton Place, London, W.1), at 7.30 p.m.—Prof. A. R. Collar: "Research at Bristol University".

ASSOCIATION OF THE WILLIAM PENGELLY CAVE RESEARCH CENTRE, in conjunction with IMPERIAL COLLEGE CAVING CLUB (in the Physics Department, Imperial College, London, S.W.7), at 8 p.m.—Mr. G. de G. Sleveking: "Painted Caves of France and Northern Spain".\*

## Thursday, February 18

PARLIAMENTARY AND SCIENTIFIC COMMITTEE (in the River Room, Savoy Hotel, London, W.C.2), at 11.30 a.m.—Annual General Meeting followed by the Annual Luncheon.

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at Battersea College of Technology, London, S.W.11), at 2 p.m.—Symposium on "Colloidal Solutes".

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, joint I.E.E./I.E.R.E. COMPUTER GROUPS (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 2.30 p.m. and 5.30 p.m.—Colloquium on "Automatic Aids to Machine Fault Finding".

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Academican M. V. Keldysh (President of the Academy of Sciences of the U.S.S.R.): "Organization of Science in the U.S.S.R.".\*

UNIVERSITY OF LONDON (at King's College Hospital Medical School, Denmark Hill, London, S.E.5), at 4.30 p.m.—Sir Robert Platt, Bt.: "Hereditary and Environment in Hypertension—the Summing Up" (Wiltshire Memorial Lecture).\*

INSTITUTION OF MINING AND METALLURGY (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. A. P. Prosser, Dr. A. J. Wright and Dr. J. D. Stephens: "Physical and Chemical Properties of Natural Copper Silicates which Resemble Chrysocolla"; Dr. A. J. Wright and Dr. A. P. Prosser: "Study of the Reactions and Flotation of Chrysocolla with Alkali-Metal Xanthates and Sulphides".

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. G. E. H. Foxon, Mr. I. R. Bishop, Mr. E. C. Tatchell, Mr. D. Walliker and Dr. J. C. Garnham: "An Expedition to the Lower Amazon, 1964".

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. R. F. Churchhouse: "The Use of Computers to Obtain Results in the Theory of Numbers".

UNIVERSITY OF LONDON (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Dr. Benno Hess (Heidelberg): "Metabolic Control Mechanisms". (Further lecture on February 22.)

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—Mr. R. F. Leggett: "Winter Construction Practices in Canada".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. O. L. Zangwill: "Experimental Psychology in Relation to Injury or Disease of the Brain". (Eleventh of sixteen lectures on "The Scientific Basis of Medicine", organized by the British Postgraduate Medical Federation).\*

ROYAL AERONAUTICAL SOCIETY (at 4 Hamilton Place, London, W.1), at 6 p.m.—Mr. H. H. Pearcey: "Swept Wing Aerodynamics".

SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDING MATERIALS GROUP (joint meeting with the Institution of Highway Engineers, at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Mr. P. D. Thompson: "The Use of Rubber in Bituminous Road Surfacing".

TELEVISION SOCIETY (in the Conference Suite, I.T.A., 70 Brompton Road, London, S.W.3), at 7 p.m.—Discussion on "Six Months Experience with B.C.C.-2".

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Médecin-Général Inspecteurs M. A. Vauzel and P. Riehet: "Le Service de Santé des Troupes de Marine et la Médecine Tropicale Française".

## Friday, February 19

BRITISH INSTITUTE OF RADIOLOGY (in the Reid-Knox Hall, Institute House, 32 Welbeck Street, London, W.1), at 2 p.m.—Radiobiology Meeting.

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 2.30 p.m. and 5 p.m.—Colloquium on "Electrostatic Precipitators".

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 4 p.m.—Dr. J. Vallance-Owen: "Modern Views of Diabetes".\*

QUEEN MARY COLLEGE (University of London) (in the New Lecture Theatre, Mile End Road, London, E.1), at 5.30 p.m.—Prof. M. W. Thring: "Mankind and Machines" (Inaugural Lecture).\*

SOCIETY OF CHEMICAL INDUSTRY, FINE CHEMICALS GROUP (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Prof. R. C. Cookson: "Circular Dichroism".

SOCIETY FOR ANALYTICAL CHEMISTRY, MICROCHEMISTRY METHODS GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.45 p.m.—Twenty-first Annual General Meeting, followed by Mr. D. W. Wilson: Retiring Chairman's Address.

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. S. Tolansky, F.R.S.: "The Microtopographies of Surfaces".

## Saturday, February 20

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. A. Mourant: "Blood Groups, Race and Evolution".\*

## Monday, February 22

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Prof. Emrys Jones: "The London Atlas".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. J. A. Saxton, Mr. J. A. Lane, Mr. R. W. Meadows and Mr. P. A. Matthews: "Layer Structure of the Troposphere".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. H. S. Kaplan (Stanford): "Unfolding Concepts of Mechanisms in Leukaemogenesis and Carcinogenesis".\*

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMOBILE DIVISION (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Transport in the Year A.D. 2000".

PLASTICS INSTITUTE, LONDON SECTION REINFORCED PLASTICS SUB-GROUP (at the Eccleston Hotel, London, S.W.1), at 7.30 p.m.—Mr. R. Calvert: "Curing Systems".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER Grade II (preferably with an interest in numerical analysis or operational research) IN THE COMPUTER UNIT, DEPARTMENT OF MATHEMATICS—The Registrar, University of Bristol, University Senate House, Bristol, 2 (February 19).

ASSISTANT LECTURER or LECTURER (preferably with an interest in microbiology, particularly in the fields of mycology and soil studies) IN THE DEPARTMENT OF BOTANY—The Registrar, The University, Liverpool, quoting Ref. CV/443 (February 26).

ASSISTANT LECTURER (preferably with experience, or an interest in space physics) IN PHYSICS—The Registrar, The University, Sheffield (February 27).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS IN CHEMISTRY, BIOCHEMISTRY, PHYSICS, ENGINEERING, CHEMOTHERAPY and related subjects—The Deputy Secretary, Academic Council, Queen's University, Belfast, Northern Ireland (February 27).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS in various branches of CHEMISTRY, including INORGANIC CHEMISTRY, CHEMICAL ENGINEERING, ENGINEERING, TECHNOLOGY, PHYSICS and allied subjects—The Registrar, The University, Manchester, 13 (February 27).

LECTURER or ASSISTANT LECTURER (applied mathematician or statistician) IN THE DEPARTMENT OF THEORETICAL MECHANICS—The Registrar, The University, Nottingham (February 27).

LECTURER (preference may be given to candidates whose interests and experience centre on the biochemistry of cellular processes in plants) IN THE DEPARTMENT OF PLANT SCIENCE—The Registrar, The University, Newcastle upon Tyne, 2 (February 27).

PROGRAMMING ASSISTANT IN THE COMPUTING LABORATORY—The Secretary of the University Court, The University, Glasgow (February 27).

TURNER AND NEWALL RESEARCH FELLOWS IN ENGINEERING, INORGANIC CHEMISTRY, PHYSICS and allied subjects—The Registrar, The University, Manchester, 13 (February 27).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS IN CHEMISTRY, PHYSICS, METALLURGY, ENGINEERING, GEOLOGY, AGRICULTURAL SCIENCE or related subjects—The Registrar of the University of Wales, University Registry, Cathays Park, Cardiff (March 1).

LECTURER IN ENGINEERING MATHEMATICS—The Secretary, Queen's University, Belfast, Northern Ireland (March 1).

LECTURER or ASSISTANT LECTURER IN MATHEMATICS—The Secretary, The University, Edinburgh (March 1).

LECTURER IN THE DEPARTMENT OF ANATOMY—The Secretary, The University, Aberdeen (March 6).

LECTURER or ASSISTANT LECTURER IN ORGANIC CHEMISTRY—The Secretary, The University, Aberdeen (March 6).

SENIOR LECTURER IN THE DEPARTMENT OF PHILOSOPHY—The Registrar, The University, Leicester (March 6).

SENIOR LECTURER, LECTURER and an ASSISTANT LECTURER IN THE DEPARTMENT OF GEOGRAPHY—The Registrar, The University, Leicester (March 6).

LECTURER, SENIOR LECTURER or READER IN ANIMAL HUSBANDRY at Makerere University College, Uganda—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (March 10).

SENIOR LECTURER or LECTURER IN THE DEPARTMENT OF MEDICINE; and a JUNIOR LECTURER or JUNIOR RESEARCH FELLOW IN THE DEPARTMENT OF PHYSIOLOGICAL SCIENCES, University of Lagos Medical School—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (March 10).

SENIOR LECTURER IN PURE MATHEMATICS—The Registrar, University of East Anglia, Earlham Hall, Norwich, NOR 05G (March 12).

READER IN ORGANIC CHEMISTRY at King's College—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 15).

SENIOR LECTURER or LECTURER (with a degree in chemistry or agricultural chemistry, and postgraduate experience, preferably in soil science or plant nutrition) IN AGRICULTURAL CHEMISTRY at Makerere University College, Uganda—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (March 15).

LECTURER IN THE DEPARTMENT OF SOCIAL ANTHROPOLOGY, School of African Studies, University of Cape Town—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1; and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa (March 26).

LECTURER IN HYDRAULICS AND HYDROLOGY IN THE DEPARTMENT OF CIVIL ENGINEERING—The Registrar, The University, Newcastle upon Tyne, 2 (March 31).

POSTDOCTORAL RESEARCH FELLOW IN ORGANIC CHEMISTRY for work which will involve chemical studies of the pteridine co-factors in amino-acid metabolism—Dr. H. C. S. Wood, Department of Pure and Applied Chemistry, University of Strathclyde, Glasgow, C.1 (March 31).

AGRONOMIST (with a degree in agriculture plus two years postgraduate training in agronomy followed by at least three years field experience in carrying out statistical experiments with field crops) in the West Cameroon, to conduct experiments on food crops and to train junior staff—The Appointments Officer, Room 301, Ministry of Overseas Development, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/33/05.

AGRONOMIST (with an honours degree in agriculture or botany, and preferably postgraduate training or experience in pasture agronomy for at least two years) in Uganda, to investigate the selection of grasses and legumes and their development in mixtures suitable for Uganda conditions and the effect of leys on soil fertility and the use of subsequent crops—The Appointments Officer, Room 301, Ministry of Overseas Development, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/183/06.

LECTURER (with a higher degree of a university in Britain and research and teaching experience) IN ORGANIC CHEMISTRY at the University of Medical Sciences, Bangkok, Thailand—The Recruitment Division, The British Council, 65 Davies Street, London, W.1, quoting Ref. 64/UNI/107.

MASTER to teach Mathematics at all levels—The Headmaster, School House, Rugby.

POST-DOCTORAL RESEARCH FELLOW (biochemist or virologist) to be a member of a small group working on the biochemistry of interferon production—Dr. D. C. Burke, Department of Biological Chemistry, The University, Aberdeen.

RESEARCH ASSISTANT (graduate with an honours degree in botany or agricultural botany) to assist with investigation of the factors which determine weed seed content of crop seeds; and a MYCOLOGIST (with a degree in agricultural botany or botany or equivalent qualifications) IN THE POTATO BRANCH to assist in the assessment of disease resistance in potatoes—The

Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

RESEARCH DEMONSTRATORS (with a good degree in botany or horticulture) IN THE DEPARTMENT OF HORTICULTURE to assist with practical classes in horticulture or plant physiology—Prof. O. V. S. Heath, F.R.S., University of Reading Horticultural Research Laboratories, Shinfield Grange, Reading, Berkshire.

# UNICAM SP.800

spectrophotometer for routine  
U.V. analysis and complete  
**automation**

The brilliant new Unicam SP.800 Spectrophotometer is setting new standards in ultraviolet and visible Spectroscopy. The widely acclaimed flat bed presentation, the beam balance smoothing cam and the unique second sample position are among the features which establish it as *the* outstanding U.V. spectrophotometer. Now, in addition, Unicam offer a set of automation accessories which provide facilities for:

**AUTOMATIC** interchange of up to 4 sample and 4 reference cells

**AUTOMATIC** re-cycling over any preselected wavelength range

**AUTOMATIC** recordings at predetermined time intervals.

## A POLICY FOR THE SOCIAL SCIENCES

ACCORDING to the Prime Minister's written answer to a question in the House of Commons on November 20, the Committee appointed, with Lord Heyworth as chairman, to review current research in social studies in Government departments, universities and other institutions, and to advise on any changes needed in the arrangements for supporting and co-ordinating this research, is expected to report in the spring. Meanwhile, the Council of the Tavistock Institute of Human Relations has issued a pamphlet which examines the whole question of social research in the wider framework of a national policy for research and development\*. Criticism of the present position is to be found, for example in the report on research in the humanities and the social sciences issued by the British Academy in 1959, in the memorandum by Prof. D. V. Glass and Prof. M. Gluckman on the social sciences in British universities which was submitted to the Robbins Committee by the British Association for the Advancement of Science (*Nature*, 196, 704 (1962)) and in the inaugural lectures by Prof. F. LaFitto at Birmingham in May 1962 and by Prof. R. K. Kelsall at Sheffield in November 1960. In this pamphlet these criticisms are discussed in the light of the findings of numerous subsequent enquiries such as those of the Robbins Committee, the Trend Committee, Lord Franks's Report on British business schools, and others from Prof. Buchanan, the Royal Institute of British Architects, the National Economic Development Council and the Organization for Economic Co-operation and Development.

The paper from the Tavistock Institute of Human Relations interprets the term 'social services' to cover the range of empirical disciplines concerned with social behaviour. It distinguishes broadly between the purely social disciplines, such as social and developmental psychology, and certain growing inter-disciplinary ones, such as social and psychological medicine, social and industrial administration, market research and management studies, operational research and systems analysis so far as they include social, psychological and academic variables. Neither the historical sciences, nor those branches of the behavioural sciences which are only indirectly concerned with social behaviour, are included.

In this description of the scope of the problem, the importance of social research in relation to the formulation of any national policy for science and technology, and even for academic growth, is unmistakable. The connexion is adumbrated by the main submission of the Council, that the priority task in supporting research in the social services in Great Britain is to foster a general development of the field as a whole. The present practice of piecemeal development is condemned as flatly as in the survey made by the British Academy. Furthermore, such a general development should be rapid rather than slow, and should be effected within the next 15 years. It must reach a certain magnitude before it can bring about the

progress made available by present knowledge, and for this purpose the Council suggests that annual expenditure should increase from £3.5 million in 1964-65 to £25 million by 1980, and that research workers should be increased from 2,000 to 11,000.

These estimates mean little except in relation to the scale and distribution of the national scientific effort as a whole. Taking the estimate of the Trend Committee for civil research expenditure through Government channels in 1962-63 of £151 million, adding £200 million for defence research, and the Treasury estimate of research expenditure by private industry in 1963 of £366 million, a figure is given of £700-£750 million for current national expenditure on research and development. The last report of the Advisory Council on Scientific Policy estimated Government expenditure in civil research in 1964-65 at £205 million, but gave no estimate for expenditure on defence research or by private industry. If, moreover, research and development expenditure in Britain reaches £1,500 million by 1980, or 3.0 per cent of the gross national product, in accordance with the target set by the National Economic Development Council, compared with 2.3 per cent in 1960, the proposed support will represent no more than 1.7 per cent of our scientific resources for social research in 1980. Even expenditure of this order falls short of the present-day expenditure of a single institution in the United States, the National Institute of Mental Health, where much of the research lies in social science. More than 3 per cent of research expenditure in the United States is now in the social services.

Unless social research in Britain is raised to such a level, serious results cannot be expected, but a change of the order envisaged depends on a widespread conviction that solutions to many of the important problems require contributions from the social sciences. This was urged by Profs. Glass and Gluckman in their memorandum to the Robbins Committee on the social services in British universities in 1962, and there have since been welcome signs of an increasing recognition of this situation and greater readiness to commit resources to it. Examples are the establishment of budgets for social research in the Home Office, the Ministry of Education, the Ministry of Health, the Board of Trade and the Central Office of Information, and the expansion of the Economic Section of the Treasury, while the subsequent changes introduced by the present Government as well as other pressures towards growth trend in the same direction. The demand for information capable of more effective statistical analysis is another factor. It is suggested in this paper that what is most needed in the United Kingdom in this field at the present time is some way of imparting a general stimulus simultaneously to the development of knowledge in the social services, for example in the universities and in specialized research organizations, and to its utilization by Government and other bodies. Accordingly, the Council of the Tavistock Institute suggests that the action to be taken first should be such as will later facili-

\* *Social Research and a National Policy for Science*. (A paper of the Council of the Tavistock Institute of Human Relations, Tavistock Pamphlet No. 7.) Pp. viii + 42. (London: Tavistock Publications (1959), Ltd., 1964.) 7s. net.

tate specific action at interdependent points. Much of the social research to be undertaken should thus grow out of attempts to help with practical problems. The line of advance is to a professional rather than a scientific discipline, as in fact has happened with medicine, engineering and architecture.

The paper then considers the problems of co-ordination and control that are presented by the heterogeneity of the social sciences and the variety and nature of the existing organizations carrying out social research. Here its analysis is sometimes rather deeper than that which marked the Trend Report on the organization of civil research generally. It finds strong reasons for keeping the new type of research organization closely linked with the executive departments directly concerned with their activities. First, an operating organization is unlikely to develop the scientific outlook imperative under conditions of increasing technological and environmental change unless it is made responsible for its own research and development. Secondly, so many Government departments are now operating on such an immense scale that the scale and heterogeneity of their tasks constitute an internal world, large and varied enough for a research and development organization to belong to it and still retain many degrees of freedom.

The paper does not underestimate the importance of scientific independence, and the Council's view is that autonomous research councils are still necessary, one being suggested for basic and another for applied research. It does not discuss the question of objectivity which has been urged as an important reason for keeping the Road Research Laboratory, for example, outside the Ministry of Transport, but it clearly does not regard the appointment of scientific advisers at a high level in a department as being, in itself, sufficient to ensure a scientific outlook. However, Lord Todd's point as to the imperative necessity of the scientist and technologist reporting at the highest level in the making of policy is duly taken. It should be noted, moreover, that it suggests that a new organization is more likely to develop effective research establishments of its own if it first collaborates with experienced outside organizations. The paper visualizes that by 1980 there may be perhaps 30 relatively small internal headquarters of about 6 senior people concerned chiefly with the identification and appreciation of problems, the head of which acts as chief social science advisor, and more than 150 field investigation groups, each with a director and a staff of about 15.

Considering next the university departments, after stressing the need for larger grants from the University Grants Committee for the development of teaching and research in the social services, the paper urges that in the short run the highest priority must be given to increasing and improving the supply of research workers in the social sciences. Here the paper assigns the first priority to graduate studies, including, however, intensive courses of one year for those with some undergraduate preparation, and of two years for those with none. Many of the best students come to hear about the social sciences only quite late, and it is neither possible nor desirable that more than a proportion of those who afterwards enter careers in social science shall have pursued, as undergraduates, the major disciplines of the social sciences. Moreover, the courses envisaged should include possibilities of acquiring practical experience, such as could be provided by attachment for periods of 3 months during the summer vacation to suitable centres in such organizations.

Because the advancement of knowledge and the extension of practice in the social sciences are interdependent, the universities must provide professional training as well as training in research, and such a development would change both the size and the character of the social science departments. Further extensive pre-doctoral programmes must be organized, so that those proceeding to a career in research undergo a thorough apprenticeship, if they are to be capable of entering into relations with those in other disciplines and of developing the broader outlook and competence essential for effective participation in inter-disciplinary programmes. For these purposes, graduate courses of two kinds, basic and professional, are envisaged, an undergraduate honours school, and other undergraduate courses given as part requirements in other departments. On the research side there would be Ph.D. candidates to supervise, various postdoctoral projects in basic research, and others of a contract character. By 1980 over the whole range of social science some 300 departments and 60 universities would be attempting these tasks, involving the equivalent of 3,000 full-time workers and an expenditure of £7 million per annum.

Discussing the special institutes for research, of which forty are envisaged by 1980, thirty (including most of the smaller ones) within the universities and ten outside, employing some 3,000 research workers and representing an expenditure of about £10 million per annum, the paper, while stressing the crucial importance of such institutes for later development, questions whether some would have more than a transitional purpose. To be effective, such an institute should have a recurrent annual expenditure of £100,000–£500,000 and a research staff of perhaps 35–60 or 70. Most of the special institutes in Britain are at present too small, comparing unfavourably with those in the United States or in Europe. Moreover, they require some basic support over and above ordinary research grants and contract fees.

It is in discussing the general system into which those various bodies would fit that the Tavistock Institute of Human Relations is most critical of the Trend Committee for its neglect of the social sciences—and of some other sciences—a neglect quite unjustified by the establishment of the Heyworth Committee while the Trend Committee was sitting. In the present paper the Council of the Institute attempts to redress that neglect by fitting its proposals for the social sciences into the framework of a general policy for the national science resources as a whole. It envisages a National Sciences Development Council to work with the Secretary of State for Education and Science, and it regards the new Science Research Council as a step in this direction, though it does not seem entirely compatible with the existence of a separate Council for Technology under the Minister for Technology. Its proposed council would recommend the allocation and utilization of the national scientific resources over the whole field of scientific endeavour. Neither a purely internal nor a purely external body is contemplated. The suggested Development Council is intended to bring Government and scientific interests together and reach common conclusions. Its logical position would appear to be, as Dr. S. Toulmin has suggested for the Advisory Council on Scientific Policy, in the Cabinet Office, directly under the Prime Minister.

The constitution suggested for this Council is interesting. Its members should include, as with the National Economic Development Council, the cabinet ministers most directly concerned, representatives of a wide range of new interests

including, besides scientific civil servants, employers' organizations, the Trades Union Congress and the University Grants Committee, together with scientific members from each of the main disciplinary groups (reflecting both pure and applied science) and learned and professional societies, including the social sciences. The Development Council would work largely through a number of commissions, each concerned with a main scientific grouping; these in turn would work with and through science research councils, applied research councils, the University Grants Committee, and other grant-giving bodies.

It is into this general pattern that the Development Commission for the Social Sciences would fit. This Commission would have as its tasks the determination of the nature and extent of available resources for social science, public and private, appraising their present-day use and adequacy, and making recommendations on the scope and direction of their future development. While responsible for recommending the total expenditure from Government resources on social research in each year or quinquennium, the Development Commission, like the other Development Commissions and the Development Council, would not itself award individual grants; its main findings would be made public for discussion and comment. The Commission would, however, strengthen the policy of according substantial social science budgets to individual Government departments, and it would also assist the series of applied research councils proposed—for example, for medicine, agriculture, natural resources, human resources, technology and industry, etc.—to foster the activities of the special research institutes.

The other main recommendation is the establishment, as one of some nine science research councils, of a Social Sciences Research Council. This Council would have as its main functions encouraging research expenditure or projects and programmes in neglected or new areas where it sees a need; fostering long-range programmes; giving institutional support through untied funds to special institutes; and provision of training fellowships, travel and sabbatical facilities, and funds enabling more social scientists from other countries to work in Britain. Whether such a Research Council should set up establishments of its own as well as award grants to other bodies is doubtful, particularly as its main function would be to ensure balanced support of the various types of research organizations.

The proposals from the Tavistock Institute are well argued and supported by analyses of the details of the proposed system which deserve the close attention of the Minister of Technology and the Secretary of State for Education and Science, even before the Heyworth Committee reports. It is not that it condemns the recommendation of the British Academy, made five years ago, and the subsequent findings of Profs. Glass and Gluckman, or shows how little has been done since the Chapman Committee reported almost two decades ago. It has constructive suggestions covering the whole field of civil science for its organization and the development of civil research, and the proposals merit attention before the recently planned changes in the structure of civil science are finally confirmed. No reader of this paper can mistake the magnitude of the contribution that social research could make to the economic as well as the social development of Britain, and no Government which fails to make effective provision for that attention can claim to have, in any real sense, a policy or a programme for economic, scientific or technical development.

## THE IDEA OF A UNIVERSITY IN TROPICAL AFRICA

African Universities and Western Tradition

By Sir Eric Ashby. (The Godkin Lectures at Harvard University, 1964.) Pp. vi+113. (London: Oxford University Press, 1964.) Boards 15s. net.; Limp 10s. 6d. net.

SOON after the Second World War, in implementing the 1945 Asquith Report on higher education in the colonies, Britain began to found universities in what were then her tropical African territories—at Khartoum in the Condominium of the Sudan, at Accra in Ghana, Ibadan in Nigeria, Makerere in Uganda and Salisbury in Rhodesia. The foundations of these new African institutions were all laid by British administrators and teachers, working in close association with the Inter-University Council for Higher Education in the Colonies and the not yet independent African Governments.

Sir Eric Ashby, Master of Clare College, Cambridge, has recently subjected the development of these African universities to a searching analysis in his 1964 Godkin Lectures in Harvard University. He seeks to trace the pattern of tension which has arisen in Africa between the English (and to some extent European) idea of a university on the one hand, and, on the other, the demands of African politicians and intellectuals that their universities shall be the product of their own soil, shall reflect their national aspirations, and fulfil the expectations African peoples have of them. His theme, he tells us, is one of universities and cultural nationalism, and he illustrates it by drawing his examples mainly from the universities at Accra in Ghana and Ibadan in Nigeria. Sir Eric's chief criticism is that we have exported wholesale to Africa our English idea of a university with little or no thought for the demands, whether in structure, function or curriculum, likely to be made on it in its new habitat. He approvingly quotes C. W. Eliot, president a century ago of Harvard University, who declared that "a university must grow from seed. It cannot be transplanted from England or Germany in full leaf and bearing . . . When the American university appears, it will not be a copy of foreign institutions . . . but the slow and natural outgrowth of American social and political habits".

So, too, must it be, argues Sir Eric, with the universities of Africa, but in fact we have hindered such a development by our cultural nationalism. He asserts that "in the past, one of the symptoms of British cultural nationalism has been an invincible confidence in the efficacy of British education, not only for home consumption but also for export" and this applies equally to our idea of a university. So we have insisted too rigidly on autonomous constitutions which debar these new universities from any functional relationship with, or any measure of control by, the State. The universities of a number of European countries, he points out, are State-controlled, but this has meant no loss of academic freedom. We have insisted, too, on very high academic standards and specialization in an attempt to adhere to what he calls the "academic gold standard", thus frustrating national demands for high-level manpower and technological expertise. As for the social function of a university, we have here exported our traditional notion that this is principally to educate an élite. The result has been that, although in the words of Dr. Nkrumah these African universities are "the heart of the nation" and essential to its progress, they and their graduates are isolated from the life of the common people in a way that has had no parallel in England since the Middle Ages. Too often to-day there is between European culture and African culture a no-man's-land, in which thousands of African graduates pass their lives, not assimilated to Europe yet strangers to their own folk.

How far are Sir Eric Ashby's criticisms justified? There is little doubt that his main point—that universities in

Africa have not adapted themselves to the needs and aspirations of African society—is substantially correct. But to infer that this was due to intolerance or cultural nationalism on the part of the British pioneers who launched the new universities of West Africa is to do them little justice and to exaggerate the situation considerably. Hindsight is always a gift of dubious value, but never more so than when we attempt to judge in near retrospect the transplantation of key institutions from one culture to another. A university, perhaps more than many other aspects of a European culture, is a focus of its value-system, and these pioneers could give of their best only in terms of the best they knew—the best of their own values. To have asked them to do otherwise would have been to expect them to do something for which they were neither qualified nor experienced. Had they agreed to do so they would have earned neither the gratitude nor the respect of their African colleagues. Adaptation is seldom the task of the innovating pioneers from the sending culture; it is the task of those from the receiving culture who take over from them, for it is based on criteria which the foreigner cannot appreciate. When President Eliot of Harvard spoke of American universities as the slow and natural outgrowth of American social and political habits, this is what he meant—and this is what is now happening in the universities of tropical Africa.

## EXTRA-MURAL EDUCATION

University Extramural Education in England, 1945-62. A Study in Finance and Policy. By Prof. S. G. Raybould. (Michael Joseph Books on Live Issues.) Pp. 207. (London: Michael Joseph, Ltd., 1964.) 42s. net.

PROF. RAYBOULD is fast qualifying for the post of keeper of the universities' conscience in matters extra-mural. His first book on the subject was published in 1951 and dealt with the period 1924-49. Now he has given us in *University Extramural Education in England* a kind of supplement covering the years 1945-62. This volume, like the first, is mainly statistical, but from the statistics Prof. Raybould adduces three major criticisms of the present position. First, the university extra-mural departments are organizing too many short courses which do not call for serious student effort; secondly, they are employing too many non-university tutors; and thirdly, that since, in view of these facts, the financial link with the Ministry of Education has so signally failed to protect university standards, it is time this link was done away with and the extra-mural departments left to stand on their own feet with such funds as their universities can be persuaded to give them.

The trouble is, I think, that in support of these contentions Prof. Raybould relies too much on the raw statistics of extra-mural courses. These statistics certainly show, for example, that there has been a disproportionate increase in the number of courses of less than twenty meetings, but they do not show that many of these short courses are conducted at a very high academic level for students who bring to the work a considerable background of previous knowledge. The statistics also show that large numbers of non-university tutors are employed on extra-mural work in a part-time capacity, but they do not reveal to what extent these tutors are employed: in some universities, at least, they play only a very minor part.

If these qualifications are borne in mind, Prof. Raybould's criticism of the Ministry of Education loses much of its force. There is a good case to be made for abolishing the present system under which the extra-mural departments have received part of their funds from their universities and part from the Ministry, and substituting a system under which, like other university departments,

they receive their funds from the University Grants Committee. This case rests, however, not on statistical considerations such as Prof. Raybould has brought forward, but on the need for the universities to have full control and full responsibility for their extra-mural teaching.

None the less, it would be foolish to dismiss the criticisms that Prof. Raybould makes as entirely without substance. Extra-mural work has been passing since the Second World War through a period of pretty rapid expansion. My own impression is that the academic quality of the work, and its reputation inside the universities, has been steadily rising. However, the statistical record, though it may not mean as much as Prof. Raybould thinks it means, does point to certain real dangers against which the universities should be on their guard, and it is of great value to have this clear and cogently argued volume to direct attention to these dangers.

T. KELLY

## SIGN-POSTS IN SOCIAL AND CULTURAL ANTHROPOLOGY

Explorations in Cultural Anthropology

Edited by Ward H. Goodenough. (Essays in Honor of George Peter Murdock.) Pp. xiii + 653. (New York: McGraw-Hill Book Company; Maidenhead: McGraw-Hill Publishing Company, Ltd., 1964.) 100s.; 12.50 dollars.

Other Cultures

Aims, Methods and Achievements in Social Anthropology. By John Beattie. Pp. xii + 283. (London: Cohen and West, Ltd., 1964.) 32s.

Social Anthropology

By Prof. Paul Bohannan. Pp. viii + 421. (New York and London: Holt, Rinehart and Winston, Inc., 1963.) 6 dollars.

IT is presumably a sign of maturity in a subject when not only volumes of the *Festschrift* order celebrate the work of leading scientists but also enough firmness has been given to the framework of theory that diverse text-books embodying it can be written.

The essays in honour of Murdock's sixty-fifth birthday rightly celebrate the work of a man who has done a very great deal to systematize and stimulate our thinking about some of the basic aspects of family and kinship structure. Even those who have disagreed at times either with his terminology or with his generalizations have been stirred to further enquiry as the result of problems he has posed. It is appropriate, therefore, that much of this book should be concerned with questions of kinship and with refinement of methods of social and cultural enquiry. Hockett's reconstructed account of the putative 'parent' of the Central Algonquian kinship system a millenium or more ago, and Lounsbury's formal model of Crow- and Omaha-type kinship terminologies, are for specialists alone. Goodenough's componential analysis of the terminology of Lapp kinship from Perhson's account is also technically difficult; as with Conklin's paper on ethnogenealogical method, the effort is interesting and rich in analytical suggestion rather than complete and convincing in final statement.

Of the many other stimulating essays in *Explorations in Cultural Anthropology* one can only indicate a handful. Rouse examines Julian Huxley's and Kroeber's ideas on evolution from an archaeological point of view, and Whiting considers how far climate has had an effect through a long chain of nursing and sleeping habits on the practice of circumcision of boys. Voget examines the way in which warfare was formerly a primary focus for integration of Crow Indian culture; whereas Pospisil, equally sociological but more tough-minded, represents the feud among an inland Eskimo group as being an

antithesis rather than a manifestation of law. La Barre gives a fascinating account of a snake-handling cult in the American South East, and Lebar a very sober statistical statement of the results of a household survey in Truk. Roberts examines in terms of the now fashionable communication and management theory the political systems of four North American Indian tribes. The regional coverage of the essays is wide, their theoretical contribution considerable. The introduction by Goodenough not only places them in a general setting but also emphasizes a modern trend of anthropology in distinguishing the observed phenomenal order of social events from the ideational order, the way in which the members of a community organize their experience.

The two text-books on social anthropology do not present analytical material with such intensity, but they are naturally much more systematic. Both are written mainly for academic use, but also provide a thoughtful introduction to the subject for those who do not wish to specialize in it. Their theoretical framework is closely parallel, which is not surprising since both authors were trained at the University of Oxford. But, whereas Beattie—with "cultures" in the title—keeps very closely to his brief for social anthropology, Bohannan—while labelling his book *Social Anthropology*—has sections on art, language and science, culture and personality as well. Both are works of intellectual calibre, but where Beattie's is sober in tone, Bohannan's is jaunty and its scholarship sometimes uneven. Both authors make some very interesting observations on the nature of their science. Bohannan, after general consideration of "the study of man", examines the task of the anthropologist in the field and the task of translation which he faces on his return. He stresses the need for analytical theory, and here argues that anthropology resembles science rather than history in its procedures. Beattie has a whole chapter on the need for theory and, like Bohannan, directs attention to the complexity of the notion that the anthropologist observes "what actually happens". Both books, in accord with present-day practice, treat of "models", and both seem quite clear on the fundamental point that the purpose of such models is to serve as aids in explanation of social reality, not as mirrors of it. In their discussion of methodology both authors, in general agreement, set out with elegance and clarity the major principles involved.

The content of the two books follows broadly the classical scope of kinship, economics, politics and religion; both too, while not denying the significance of the time dimension for all dynamic investigations of institutions, still rather conservatively have a section at the end specifically labelled "Social Change". Ethnographically, perhaps, the range is rather narrow; Africa has pride of place in the examples given, and though Bohannan has the wider coverage even his societies cited include none from Middle or South America.

Differences in their treatment are partly idiosyncratic and partly due to national tradition, exemplified by Bohannan's bow to the theory of cultures and personality and that of social evolution. Bohannan's book is curiously uneven in its handling of some topics. The section termed "The Image of the Unknown", less than fifty pages in all, is occupied by a chapter on the history of anthropological and sociological thinking about magic, science and religion (but no mention of Lynn Thorndike) and another of equal length on witchcraft, whereas "Tribal Religions", of which the Manus of the Admiralty Islands are the sole example examined in detail, are compressed into a dozen pages. "Sacrifice", which "lies at the heart of African religion", is dealt with in four lines. Some thoughtful observations on economic anthropology are marred by the view that it is only Karl Polanyi who has made it possible to investigate allocation cross-culturally "without disturbing the science of economics and without becoming its slave" (p. 213). The material on politics, government,

law and warfare is, as we might expect from Bohannan's earlier work, of high quality. An interesting section on "the network of agreements" begins with a useful summary of material on contracts and associations and another on rank and other systems of inequality. An examination of "the chimera of race" in this context, presumably with the idea that it fits the treatment of social inequality, is less successful. "Negroes and whites exist in the United States *in the same way* (my italics) that the Republicans and Democrats exist or Catholics, Protestants and Jews exist. They are social categories that influence action" is a statement that strikes oddly to the readers of, say, the recent work of James Baldwin. However accurate may be the notion that human races are social categories based on observable physical differences, it seems rather excessive to state that "race" is the modern Western idiom for pariah groups (pp. 205-6).

Modern social anthropology has a long tradition of interest in the ideas, beliefs and values of the peoples examined. But it is only during the past decade or so that these have received so much overt systematic and detailed attention. Beattie's book rightly stresses this concern, and shows how social anthropologists are interested in symbols and symbolic thinking at two levels of analysis, the level of meaning and the level of social action. This he exemplifies in many fields, including the political and the economic as well as the magical and religious. But this preoccupation has led even Beattie, well known for his solid and perceptive field research, to underplay the quantitative side of empirical field data. "No amount of statistics", he tells us, "will help us to understand a people's conception of spirit or other notion of substance or even what they understand by marriage or by their different categories of kinship". Of course statistics alone are useless; rightly Beattie points to the need for imaginative effort in such understanding. But imaginative effort alone is no substitute for systematic field work. It is precisely because of the lack of adequate statements of the frequency with which terms are used and actions performed and of their distribution in different sectors of the population that we are still vague about the meaning of even some of the best-known ethnographical formulations about a concept of spirit or a notion of substance. But Beattie does give systematic and thoughtful analysis to a range of beliefs and values in institutions such as ancestor worship, magic and sacrifice.

All three books are to be recommended to readers who wish to know more of social anthropology: Beattie's as a straightforward text-book of a thoughtful kind; Bohannan's as a sparkling if somewhat erratic commentary; the essays edited by Goodenough for the specialist who wishes to understand more in depth about some significant trends in modern anthropology.

RAYMOND FIRTH

## AN ENCYCLOPAEDIA OF ORNITHOLOGY

### A New Dictionary of Birds

Edited by Sir A. Landsborough Thomson. Pp. 928+48 plates. (London and Edinburgh: Thomas Nelson and Sons, Ltd., 1964.) 105s. net.

IN celebration of its centenary in 1959 the British Ornithological Union dispatched expeditions to the Comoro Islands and to Ascension Island and undertook a third enterprise of a different character in the launching of *A New Dictionary of Birds*. It was a very good idea and it has been brilliantly carried into effect under the editorship of Sir Landsborough Thomson. It may well come to rank as the best English bird book of the twentieth century.

The editor has himself contributed about forty articles of encyclopaedia length on major subjects of general interest and, in addition, has taken on his own shoulders the burden of defining the terms used in modern ornithology and of writing scores of short articles on a wide range of subjects. This comprehensive book is thus both a new dictionary and an encyclopaedia. But it is more than the indispensable work of reference to be consulted on occasion in an impersonal library. The longer articles designed for "deliberate reading" will make it the constant companion of all those seriously interested in birds as bird-watchers or scientific ornithologists or as biologists concerned in some specialized aspect.

Here they will all find the results of much exciting scientific investigation and a wealth of field observations.

The editor's treatment of names and technical nomenclature puts much disputatious (but not scientific) learning into perspective.

In his discussion of English names he may possibly go too far in saying that the expressions a "charm" of goldfinches or even a "fall" of woodcock have become entirely obsolete, at least in local speech, and can be taken, if used, as only half-serious. But one can unreservedly agree that "to take a minority view in a matter of convention is merely a nuisance".

In paying a tribute to the pioneering publication of Alfred Newton, this work justly claims to be new in scope and plan. It has taken full account and advantage of the great growth in specialized investigations since his day so as to embrace a vast accumulation of new knowledge, and the value of the interplay of disciplines clearly emerges. The 'schematic arrangement' of the major articles on general subjects, listed under that description, is a guide to the entries designed for deliberate reading. Together with the following list of those on main bird groups, it is the key to the basic plan of the book.

The editor adopts the classification of Peters's *Check-List of Birds of the World*, based on the system proposed by Wetmore, and, at the end of the volume, there is an alphabetical list of genera.

The general subjects include form and function, systematics and evolution, distribution and ecology, ethology and birds and man. Within these groups, every topic of importance to ornithologists is separately treated, fully under most headings and adequately under all. Most of the contributors are British, but for some widely spread groups of birds it has often been appropriate to invoke the aid of foreign experts. Similarly, subjects like vegetation and climatology, and some of the more anatomical and physiological essays, have gained in authority from being entrusted to distinguished scientists who are not themselves necessarily concerned primarily with birds. Whatever subject the reader may select, the useful and abundant cross-references carry him on from one enlightening article to another and assist him to pursue his enquiry when the encyclopaedia treatment has split the main topic among several authors. The *New Dictionary of Birds* differs from its predecessor in this fundamental respect of diverse authorship (nor would any other course have been practicable) and in giving far less space to historical matter. It reflects a real shift in the range and direction of ornithological investigation since the end of the past century. Newton himself emphasized the fact that ornithology meant much more than a "perfect taxonomy". But, on the other hand, Sir Landsborough reminds us that, writing in 1903, Ridgway still regarded anatomy and systematics as "scientific", life histories and habits as merely "popular". Nowadays, in taxonomy itself the *New Dictionary of Birds* shows that "the trend is not all towards the laboratory" and that the investigation of the living bird and its behaviour provides material which the taxonomist needs to consider.

The treatment of general subjects may be illustrated by almost any example. The series of articles on the senses

of birds, for example, include a covering introductory note by the editor. As he observes, experiment in this field is difficult and analogies with man may be misleading. In the separate examination of particular senses, it is concluded that taste may play little part in the selection of food, which appears to depend more on shape and tactile response. Smell also requires experiment with a wider range of stimuli before any definite conclusion can be reached. The oil bird (*Steatornis caripensis*) is credited with a very well-developed olfactory apparatus and is said "probably" to locate fruit-trees by their scent. It is an isolated member of the Caprimulgiformes, is gregarious, nocturnal, lives in caves and has a faculty of echo-location.

The nocturnal kiwi is another taxonomically abnormal species and has the olfactory lobe of the brain well-developed. But the evidence for its sense of smell is not accepted as convincing. The nasal organs of the turkey vulture again suggest a well-developed olfactory sense; yet it is unable to detect carrion if it is covered.

Other groups of birds have been thought to possess a sense of smell, including ducks and geese. This view was held by the Dutch keepers who insisted on approaching their decoys with burning sticks in their hands lest the birds should get scent of human beings. To some who have accompanied them it seemed that the ducks were alerted by sound rather than scent.

There is no doubt of a bird's keenness of hearing and acuity of vision. Diurnal, as distinct from nocturnal, birds also possess colour vision. Here the special contributor concludes that the range of colours visible to them is about the same as in man and that the ability to distinguish one hue from another is similar. Some special adaptations of vision in birds are dealt with.

In the remaining sense of touch it has yet to be shown whether rictal bristles have any sensory function. Migration, a different major subject and one on which the editor has long been an authority, provides another instance of interesting treatment. Though no longer "a mystery scarcely penetrated", as Newton described it, it is one far from being completely solved. Many old ideas have been shown to be ill-founded. Dismissed as equally ill-founded is the more recent notion that birds are sensitive to variations in magnetic forces. Magnetic sense is, in fact, defined, with a Johnsonian touch, as a faculty "sometimes hypothetically invoked, but not known to exist". Nor is there evidence of the existence of any organ by which such variations could be measured. The editor's own important article on migration discusses what is known as to the manner in which birds migrate, and the crucial problem of their ability to orientate themselves in the absence of previously known landmarks is examined by Dr. Geoffrey Mathews, who writes on navigation. Briefly, he regards a power of simple compass orientation as certainly established and a more complicated form of grid navigation as "plausible" but not proved, both capacities being based on celestial clues in the sun and the star pattern.

The articles on radar and time measurement are relevant, and it is interesting to find a separate article on Moon-watching as a means of examining migration. Newton records that, at the end of the nineteenth century, observations of the Moon through an astronomical telescope at Princetown showed large numbers of birds passing at a height of one or two miles. As a result of various means of visual observation, and through radar and ringing, a great deal is now known about the modes of migration and the routes which birds follow.

In other articles, the allied topic of irregular irruptions of certain species is interestingly discussed, as is the difficult and even controversial question of the factors regulating bird populations. The scientific basis of this regulation is not yet fully understood, and Dr. Lack, writing on population dynamics, though adhering to his view that animal numbers are regulated by density-

dependent factors, admits that the whole subject is "still in its infancy".

Finally, a series of articles relating to birds and man includes all the issues arising from modern conceptions of conservation and protection, and the dangers attendant on introductions of exotic species.

For many years and even decades this impressively authoritative addition to ornithological literature will hold the field. Long before the British Ornithological Union celebrates its second centenary and contemplates another new dictionary, many and perhaps most of the unresolved scientific questions so ably discussed and now left open will have found their answer. Whether the variety, range and abundance of the world's birds and of habitats suitable for most of them will still be as fascinating for ornithologists to study and bird-watchers to enjoy a century hence is a speculation on which it is not possible to embark without misgiving and even anxiety.

HURCOMB

## EARTH SCIENCES

### The Planet Earth

Edited by Prof. D. R. Bates. Second edition, revised and enlarged. Pp. vii+370. (London and New York: Pergamon Press, 1964.) 42s. net.

### The Earth Sciences

By Prof. Arthur N. Strahler. (Harper's Geoscience Series.) Pp. xii+671. (New York, Evanston, and London: Harper and Row, 1963.) 75s.

### Introduction to Satellite Geodesy

By Prof. Ivan I. Mueller. Pp. xxi+415. (New York: Frederick Ungar Publishing Co.; London: Constable and Co., Ltd., 1964.) 15 dollars; 120s.

### Gravitation and Relativity

Edited by Dr. Hong-Yee Chiu and Dr. William F. Hoffmann. (Physical Investigations of the Universe.) Pp. xxxv+353. (New York and Amsterdam: W. A. Benjamin, Inc., 1964.) 15.75 dollars.

THESE four books are of considerable interest to workers in the Earth sciences.

*The Planet Earth*, edited by Prof. Bates, has been published in a second edition. It is a useful survey in 18 chapters of the separate aspects of the physics of the Earth and its environment. Although in the preface to this edition it is stated that there has been considerable revision of the chapters to bring them up to date, there has, in the interval of six years, been revolutionary advance in many of the topics under discussion and the revision has in many cases not been sufficiently thorough. However, it is a book which should be read by all students of geophysics.

*The Earth Sciences*, by Prof. Strahler, is of a much more elementary level and is intended as an introduction to be read by students in American university departments of geology. It is extraordinarily well illustrated with much useful graphical presentation and some remarkable photographs. What is perhaps important in relation to teaching in geology departments in Britain is that geophysical and astronomical topics are tackled in detail and I think the treatment is successful. The presentation of meteorological, astronomical and oceanographical principles to students of geology who often have not specialized in physics and mathematics is difficult, and Prof. Strahler is to be congratulated on his attempt to present physical explanations in simple terms by very excellent illustrations.

The other two books are of a more specialized nature. *The Introduction to Satellite Geodesy*, by Prof. Mueller, is of great importance. The accurate determination of the small divergences of the Earth from hydrostatic equilibrium

will probably provide the solution to many of the more important questions in geophysics during the next few years. The question whether or not convection currents are occurring in the mantle of the Earth, and if so what their distribution is, is likely to be solved in this way.

The book by Dr. Chiu and Dr. Hoffmann on *Gravitation and Relativity* may seem to have little interest for the geophysicist. However, in the past the investigation of the solar system has revealed fundamental laws of physics which could not easily have been discovered in the laboratory. The geophysicist should not always assume that he is simply concerned with the application of the known laws of physics to explain natural phenomena. The distinguished contributions in the book by Prof. Dicke and Prof. Wheeler concern fundamental difficulties in the theory of gravitation, to the discussion of which geophysical data on the evolution of the Earth-Moon system may still produce a notable contribution.

S. K. RUNCORN

## ASPECTS OF RELATIVITY

### The Theory of Space, Time and Gravitation

By V. Fock. Translated from the Russian by N. Kemmer. Second revised edition. Pp. xii+448. (Oxford, London, New York and Paris: Pergamon Press, 1964.) 100s.

THE first edition in English of *The Theory of Space, Time and Gravitation*, published in 1958, was greeted as an important and original contribution to the literature; in subsequent years Prof. Fock's book has continued to be held in high regard, proving itself worthy of its initial acclaim. The recent publication of the second revised edition of this masterly work is indeed to be welcomed.

Able translated from the Russian by Prof. Kemmer, this book includes, within its role as a text-book for the graduate student in theoretical physics, the author's own powerfully argued and highly distinctive views and interpretations of the subject of relativity. It is a thorough exposition of what are usually called the special and general theories, although Fock insists that these are misnamed. Using the word 'relativity' to denote an invariance in the description of physical processes in different frames of reference, Fock justifies instead the nomenclature 'the theory of relativity' and 'the theory of gravitation', by pointing out that the principle of relativity is directly related to uniformity and that Galilean space has maximal uniformity.

The first four of the seven chapters of the book are devoted to the development of the theory of (special) relativity, including its formulation in tensor form. The remaining chapters, rather more controversial in character, deal with Fock's own interpretation of the foundations and principles of Einstein's theory of gravitation.

In its non-cosmological form, this is based on the hypothesis that the geometrical properties of real, physical space and time correspond to Riemannian, rather than Euclidean, geometry, any deviation from the pseudo-Euclidean form appearing as a gravitational field. Throughout the work, Fock is concerned with ensuring the uniqueness of this result, and he deals with the problem of boundary conditions by combining with the above hypothesis the assumption that there is an insular distribution of masses, so that the geometry at points far removed from the masses is Euclidean. (When the cosmological problem is briefly discussed in Sections 94 and 95, this assumption is replaced by that of a uniform distribution, which leads to a Friedmann-Lobachevsky space.)

The field equations then follow from a generalization of Newton's laws, and the remainder of the book deals, in the main, with the derivation of the equations of motion and with gravitational potentials. Much of the complexity

of the resulting equations is reduced by Fock's use of a preferred system of co-ordinates, which he calls 'harmonic'. Fock accords a particular significance to harmonic co-ordinates (each of which satisfies a linear, generally covariant, equation), apparently because a harmonic system is uniquely determined to within a Lorentz transformation, under suitable supplementary conditions.

The changes effected for the new edition are summed up in the author's preface as follows: "The second edition differs from the first by some additions and reformulations. The question of the uniqueness of the mass tensor is treated in more detail (Section 31\*) and is illustrated by two examples (Appendices B and C). The notion of conformal space is introduced and used as a basis for the treatment of Einsteinian statics (Sections 56 and 57). Greatest care has been applied to the formulation of the basic ideas of the theory and to the elucidation of those points in which the author's views differ from the traditional (Einsteinian) ones. Thus, in order to discuss the general aspects of the relativity principle Section 49\* has been added".

Prof. Fock's unorthodox views, expounded with a forceful clarity, undoubtedly help to advance our understanding of the theory of gravitation, making this a work of major importance.

ELIZABETH HILTON

## STELLAR STATISTICS

### Statistical Astronomy

(Dover Publication No. 301.) By Robert J. Trumpler and Harold F. Weaver. Pp. xxi+644. (New York: Dover Publications Inc.; London: Constable and Co., Ltd., 1962.) 24s.; 3.00 dollars.

*STATISTICAL Astronomy* deals with statistical investigations of the system of stars, and concentrates on such problems as the space distribution of stars, the distribution of stars on the *H-R* diagram, the distribution of stellar velocities, and the phenomenon of galactic rotation. The statistical techniques involved are generally elementary in principle and tedious in application, and are fully developed in the first part of the book.

On reading such a detailed account and development of the subject as is presented here, one cannot help feeling that statistical astronomy has absorbed a great amount of the energy of astronomers and produced singularly few results. The authors should be fully aware that, because of the existence of interstellar dust, any star-counts can only lead to a 'local' picture of the star system, and a very distorted picture at that, if allowance is made only for a 'smooth' distribution of dust clouds; yet the book spends more than 120 pages doing just that. Shapley's classical investigation of the globular clusters which first led to a correct assessment of the star system is not mentioned, presumably because it involved too little statistics. Again, the construction of *H-R* diagrams for stars in the solar neighbourhood involves much statistical manipulation and takes up a correspondingly large space in the book, yet it is nothing like as useful as the *H-R* diagrams for star clusters, which involve little statistics and receive correspondingly brief treatment. In the field of stellar motions, the book gives a good description of Kapteyn's two-stream model and Schwarzschild's ellipsoidal model; it then develops the latter along Charlier's method of moments. The treatment is complete from an observational point of view, but the most intricate part of the mathematical problem (p. 66) is shirked by a facile reference to the two-dimensional case. It omits to mention Ambarzumian's method of determining the distribution of space motions without assuming a model. It seems that the best part of the book is the part dealing with the phenomenon of galactic rotation. Oort's original theory and Bottlinger diagram are set out very clearly, and are further developed in a sound manner. This subject is

mainly kinematical and dynamical in character, and is only marginally statistical.

There is an unfortunate idea among astronomers that statistical astronomy is a dull subject, that nothing of value has come out of it that cannot be improved on by non-statistical means. This is not true. There are exciting problems in this field, and these problems can be nothing but statistical, to witness, the distribution of interstellar matter and the clustering of galaxies. It is a pity that the only book in English that bears the title of 'statistical astronomy' fails to include these more exciting problems, and presents the subject in a rather unattractive manner by confining itself to problems in stellar astronomy. But, since there is also a dearth of text-books on stellar astronomy, this book is quite worth its Dover edition price from the point of view of the serious student.

T. KIANG

## A BIOLOGIST LOOKS AT MAN

### Genetics and Man

By Prof. C. D. Darlington. Revised edition of *The Facts of Life*. Pp. 382+8 plates. (London: George Allen and Unwin, Ltd., 1964.) 42s. net.

IN the preface of the first edition of his book *The Facts of Life*, published in 1953, Darlington defined his purpose, "to show the immense possibilities which await the application of the elementary principles of heredity to the great problems of society". In the preface of the revised edition, retitled *Genetics and Man*, Darlington explains that it has been necessary to abridge the old text in order to make room for new material. Certainly the new title is more apt, because the volume does not contain much information about what are popularly considered to be the facts of life.

The first comment to make about this book is that it is most entertaining. Geneticists, particularly those concerned with human genetics, can complain that some of the arguments are developed by an oversimplification of the facts. The biologists may be annoyed by occasional lapses into teleology, "The fly therefore has to reduce recombination" (p. 120). The stylists may appreciate the musical analogies, "mitosis is a symphony consisting of four movements" (p. 69), but find some of the constructions rather tortuous. The cynics will comment on a certain naïvety in the approach to problems involving human sexual relationships. There are one or two places where the reader is arrested by prejudice, for example, in a discussion of the education of normal women, "Girls are therefore prepared for a life which most of them will never follow, or wish to follow, and which it would be disastrous to the community if they did follow" (p. 317). This appalling state of affairs is attributed to the great influence that the "positively homosexual type of women" (p. 316) has had on the educational system!

In order to develop the theme of genetic determinism, the reader is taken smoothly through the advances in genetics from Moses via Mendel to molecules. There are interesting excursions into the history of forgeries that disturbed the scientific world. Having laid the foundation, Darlington philosophizes on the importance of the genetic background in all human situations. Advances in medicine have so reduced the untreatable causes of morbidity and mortality that medical practitioners have become increasingly aware of the importance of the family history of their patients—if not their genes. So Darlington possibly overstates the case when he writes, "And, when medicine wakes up to the existence of biology and rediscovers a philosophy, the genetic individual will be restored to his place" (p. 243).

These criticisms do not, however, seriously detract from the merits of a book that can be read both for pleasure and profit by laymen and scientists.

SYLVIA D. LAWLER

## College Chemistry

An Introductory Textbook of General Chemistry. By Prof. Linus Pauling. Third edition. Pp. xxiv+832. (San Francisco and London: W. H. Freeman and Company, 1964.) 50s.

THE third edition of *College Chemistry* brings in a wider range of topics, including a final chapter on the thirty-four fundamental particles. The theory is gradually and clearly introduced and includes some more advanced topics, such as Boltzmann's theorem from both the classical and quantum aspects. The sections on molecular structure, based on the valence bond and resonance theories, are clear and provide numerical data and graphs which add to their usefulness. The theory of metals and alloys is dealt with. Statistical mechanics rather than thermodynamics is mainly emphasized, but free energy and entropy are used in connexion with equilibrium; otherwise enthalpy changes are given prominence. The descriptive chemistry, including some organic chemistry, is adequately presented for a book of this character, and some attention is given to the history of chemistry. In discussing the elements and compounds, emphasis is laid on systematization, but sufficient detail is given to make the information worth while. The reaction for the preparation of chlorine dioxide given on p. 371 is incorrect. On p. 377 iodine dioxide is said to be paramagnetic and hence to have the formula  $\text{IO}_2$  and not  $\text{I}_2\text{O}_4$ ; it is in fact diamagnetic and the formula cannot be  $\text{IO}_2$ . There is a good description of the transuranium elements and related subjects. There is no doubt that this book, which has been carefully planned and written, will continue to enjoy the popularity which it fully deserves.

J. R. PARTINGTON

## Order-Disorder Phenomena

By H. S. Green and C. A. Hurst. (Monographs in Statistical Physics and Thermodynamics, Vol. 5.) Pp. x+363. (London and New York: Interscience Publishers, a Division of John Wiley and Sons, Inc., 1964.) 105s.

*ORDER-Disorder Phenomena* is Volume 5 in a series of monographs edited by Prof. Progogine. So far, this series has produced one volume which is a very advanced text-book and four learned monographs. One may ask at this stage whether the series really provides scientists and engineers with "a comprehensive treatment of the basic methods of statistical mechanics" as is claimed. I seriously doubt whether this aim has been realized, and the relatively excessive price of the volumes in the series indicates also a lack of conviction on the part of the publishers.

If, however, one considers this series to be aimed purely at the specialists, there is a great deal to recommend it since the volumes in the series are well written by authorities in the fields covered. *Order-Disorder Phenomena* is no exception, as both authors have made significant contributions to the investigation of the subject.

The title of the book is slightly misleading, for it is essentially concerned only with a discussion of the so-called Ising model and even then mainly with the case of the two-dimensional lattices. Within this restriction the treatment is extensive and covers most recent developments. References to other work are, as seems to be an increasing tendency, patchy. The early paper by Lassetto and Howe in which the matrix method was proposed, independently of Kramers and Wannier, is, for example, not mentioned. Not very surprisingly, great emphasis is placed on the Pfaffian method developed by the authors. Unfortunately, recent developments and simplifications by Rumer and by Schultz, Mattis and Lieb occurred too late to be included.

The book starts with a general discussion of phase transitions and a statement of the Ising problem. The authors then show how far this model is applicable to the theory of ferromagnetism, antiferromagnetism and

ferrimagnetism, to the theory of binary alloys and to the discussion of lattice models of fluids. A discussion follows of the rectangular two-dimensional Ising lattice and the Pfaffian theory applied to this case. Then come a chapter on the general theory and a chapter dealing with other lattices, such as the triangular and hexagonal lattices, and also discussing correlations and spontaneous magnetization. In conclusion, other methods and a few outstanding problems are discussed and six mathematical appendixes complete the book.

The book is well written and can be recommended as an introduction to various approaches to the Ising model.

D. TER HAAR

## Zahlenwerte und Funktionen aus Physik, Chemie, Astronomie, Geophysik und Technik

Von Landolt-Börnstein. Sechste Auflage. Zweiter Band: Eigenschaften der Materie in ihren Aggregatzuständen. 2 Teil: Gleichgewichte ausser Schmelzgleichgewichten. Bandteil c: Lösungsgleichgewichte II. Bearbeitet von J. D'Ans, D. Jänchen, E. Kaufmann und C. Kux. Herausgegeben von Klaus Schäfer und Ellen Lax. Pp. viii+731. (Berlin, Göttingen, Heidelberg: Springer-Verlag, 1964.) Moleskin 388 D.M.

SUCH is the credit rating of Landolt-Börnstein that it is not necessary to do more than to indicate the scope of this book. It opens with a continuation, from the earlier volume, of data on solubility equilibrium of solids and liquids, limited here to organic compounds. The survey of binary systems occupies rather more than half the pages; the arrangement is not difficult to follow, but to assist there is a very full index, based on molecular formulae. To say that this part is amplified by 321 diagrams does not give a true idea of the extent of the use to which these are put, for nearly all illustrate several systems, sometimes as many as a dozen; a few give the impression of being rather overcrowded. Information on about 300 ternary and higher systems is limited to literature references.

The remainder of the space is devoted to equilibria in systems having immiscible liquid phases. After a general survey, presented in tabular form, ternary and quaternary systems are dealt with in detail, each illustrated clearly with diagrams. The last part tabulates distribution coefficients in two phase systems; most of the solutes are organic but not all; water is one of the solvents in the majority of the systems recorded.

As is acknowledged, some information has been supplied from outside sources, and one cannot but admire the manner in which it has been collected from world-wide literature and then collated. It appears to have been overlooked that *NN*-diphenylacetamide and *N*-acetyldiphenylamine are identical; however, the arrangement brings the two entries next to one another on p. 359, so confusion is minimized.

B. A. ELLIS

## 1963 Transactions of the Tenth National Vacuum Symposium of the American Vacuum Society

October 16, 17, 18, Boston, Massachusetts, U.S.A. Edited by George H. Bancroft. Pp. xxi+510. (New York: The Macmillan Company; London: Collier-Macmillan, 1963.) 23 dollars; 172s.

THE extent of the enormous surge forward in vacuum technology and its applications in the United States during the past decade can be well appreciated by an examination of this handsomely produced volume containing 93 papers presented to 1,600 delegates at the tenth National Vacuum Symposium. The scale of activity is much greater than in Britain, and it is particularly significant that considerable research is in progress in American universities, whereas in British colleges work on vacuum, especially in its engineering aspects, is comparatively slight.

This American effort has been greatly stimulated by their space programme. Apart from the problems of the design of space simulators, much research is recorded here on materials from the points of view of lubrication, friction and wear *in vacuo*, effects of ion bombardment, solar and reactor radiation (the latter anticipating the possible development of nuclear-reactor powered rockets) and gas sorption and desorption. Freeze-drying, though a well-established technology, is being actively developed, particularly to reduce costs in application to food dehydration. The new techniques of sorption and cryopumping are well represented by nine papers and there are five papers on getter and ion pumps. The vapour diffusion pump, which has been a vital tool in vacuum technique for half a century, so far from being ousted by newer methods, is becoming widely accepted in ultra-high vacuum systems now that it is clearly realized that its ultimate pressure is theoretically vanishingly small, and is therefore the concern of nine research papers. There are twenty papers on vacuum measurement representing the growing body of knowledge about ionization gauges, gas analysis by mass spectrometer methods and the problems of calibration. Thin film technology is the concern of thirty-six papers, classified under sputtering, semi-conductor films, film preparation and film properties.

These *Transactions of the American Vacuum Society*, appearing annually, are the best reviews available of the most recent vacuum technology. The problem exists of the conference where so many papers are read, often with too little attention directed to presentation both at the lecture and in the final written account, that the audience and the reader tend to suffer severe mental indigestion. However, the American Vacuum Society is undoubtedly a progressive and imaginative body from which consideration of this problem can be expected. J. YARWOOD

### Packing and Covering

By Prof. C. A. Rogers. (Cambridge Tracts in Mathematics and Mathematical Physics, No. 54.) Pp. viii+111. (Cambridge: at the University Press, 1964.) 30s. net; 5.50 dollars.

SUPPOSE that a large box is filled with spheres of equal size. The proportion of the volume of the box which is occupied depends, of course, on the closeness of the packing; it is possible to pack the spheres in such a way that this proportion is as high as  $\pi/3\sqrt{2}=0.74$ , but it is not known whether this is the closest possible packing. This is a very typical packing problem, and the fact that, despite its simple formulation, it continues to defy the efforts of mathematicians to solve it shows that the theory of packing is a non-trivial, and indeed a challenging, branch of pure mathematics. It is also important because of its connexions with the 'geometry of numbers' and hence with number theory.

The same problem can be posed in  $n$  dimensions. When  $n=2$  the answer is known; the closest possible packing of circles fills a proportion  $\pi/2\sqrt{3}=0.91$  of the area of the plane. When  $n\geq 4$  the best packing is not known, but certain packings thought to be quite good have been found. For example, in 12 dimensions Coxeter and Todd have a packing which fills a proportion  $\pi^6/19,440=0.05$  of the space.

Prof. C. A. Rogers gives a fascinating account of these problems in *Packing and Covering* and of the known results, particularly of those which give (incomplete) information when the dimension  $n$  is large. He is concerned not only with spheres, but also with more general bodies and with certain restricted types of packing.

A very similar problem is that of covering. Suppose, for example, that one tries to cover a region of the plane of large area  $A$  with circles of unit area. The minimum number required will be approximately  $1.21 A$ , where the number  $1.21$ , or more exactly  $2\pi/3\sqrt{3}$ , is a measure of the necessary overlap. The analogous problem in 3

dimensions is unsolved, but the number which must replace  $1.21$  is known to lie between  $1.43$  and  $1.47$ . Here again the problem can be generalized, and there are a few results where the dimension  $n$  is large.

It is, however, true that most of the interesting problems are unsolved, and one may hope that Prof. Rogers's well-written survey of the field will stimulate mathematicians to a renewed attack, while leaving them under no illusions about the difficulty of their task. J. F. C. KINGMAN

### An Introduction to the Solidification of Metals

By Dr. W. C. Winegard. (Institute of Metals Monograph Series, No. 29.) Pp. x+98+10 plates. (London: The Institute of Metals, 1964.) 42s.

THIS short monograph contains an elementary and concise survey of present-day knowledge on the solidification of metals. The book has been written for undergraduate students and those metallurgists and scientists who have no previous knowledge of the subject. Dr. W. C. Winegard has succeeded admirably in condensing much information which was only previously available in original papers and research reports.

The book attempts to relate the structure of the freezing solid with the conditions that prevail during the process of solidification. The opening chapters cover the relevant properties of solids and liquids, the thermodynamics of nucleation and the subsequent process of crystal growth in pure metals. An important chapter is devoted to the consideration of alloy systems and phase diagrams, where emphasis is placed on the concentrations that exist at the solid-liquid interface. These ideas are then used by Dr. Winegard in a discussion of the growth structures that occur when alloys solidify, the concept of constitutional undercooling being introduced, and there follows a review of growth structures in solid-solution alloys. Later chapters deal with segregation, eutectic growth, zone-refining and techniques available for growing single metal crystals from the melt.

The presentation of the material has been well thought out and the book provides a valuable introduction to more advanced reading on the subject.

D. T. TURNBULL

### The World of Birds

A Comprehensive Guide to General Ornithology. By James Fisher and Roger Tory Peterson. Pp. 288. (London: Macdonald and Co. (Publishers), Ltd., 1964.) 105s. net.

SCIENTIFICALLY, this book is light-weight, since it is mainly a work of interpretation and, although it has a bibliography, the entries are not specifically tied to the text. But, as a work of interpretation and as an aesthetic production, it will find a wide and appreciative audience. Birds lend themselves to artistic portrayal, and ornithologists will find a great wealth of material, on birds from all parts of the world, lavishly spread before them in the inimitable style of Roger Tory Peterson. The text by James Fisher deals with all aspects of bird biology under subject headings, and the illustrations are deployed to give the richest possible commentary to the text. The long series of maps depicting the world distribution of many families of birds, including those known from fossil material, will be a mine of comparative information to those ornithologists who have specialized in their own regional avifaunas. Finally, the sections dealing with species which have become extinct and those which are threatened with the same fate are particularly valuable. In addition there are useful chapters on technical aids and on the co-operative approach to the investigation of such subjects as migration, nest-recording and census work.

The standard of reproduction and presentation is first-class and, despite the high selling price, this is a book which will appeal specially to the talented amateur.

H. N. SOUTHERN

## MOLECULAR BIOLOGY IN CHINA

By PROF. M. ERRERA

Laboratoire de Biophysique et Radiobiologie, Faculté des Sciences,  
Université libre de Bruxelles

NOT having been a regular reader of *Scientia Sinica* or of other Chinese scientific journals, my first visit (together with five other Belgian scientists) to Chinese institutions was an experience as stimulating as visiting a museum full of recently discovered works of art or walking in a park built where there were slums half a dozen years ago. The Chinese people are advancing in all fields simultaneously, and the field of science is not remaining behind any other. Of course, the challenge of educating the people is tremendous and the problems with which Chinese scientists are involved are extremely complex: both technical and scientific education badly need to be developed with the greatest possible speed. This the National Science and Technological Commission, headed directly by one of the vice-premiers, and both the Academia Sinica and the Chinese Academy of Medical Sciences, have clearly understood: they have taken the necessary steps to make rapid progress. The leading scientists of the country have been re-grouped in the various institutes of the Academia Sinica or the Academy of Medical Sciences, which have started work mainly in Peking and in Shanghai, but also in the other big cities. The main responsibility of these groups is to develop research and graduate teaching, but some of them are also responsible for writing up-to-date Chinese text-books to be used in the universities. Members of the Biochemical Institute in Shanghai provide an example.

## Protein Chemistry

*Enzyme structure and function.* The approach is both theoretical and experimental: Tsou Chen-lu (Institute of Biochemistry, Academia Sinica, Shanghai) has examined data from the literature relating the modifications of functional groups of a variety of enzymes to their biological activity and has established equations from which the number and types of essential groups involved can be calculated. This defines the best experimental conditions for obtaining further results. This investigation covers many hydrolytic enzymes, some of which are now being examined experimentally, and it has led to the suggestion that, in many cases, two enzyme substrate intermediates are involved, one of the Michaelis type and the other an acyl enzyme intermediate in the case of proteinases or esterases. This type of mechanism has been generalized to other systems and shown to be compatible with data from present-day literature<sup>1,2</sup>.

A certain number of proteolytic enzymes have been approached experimentally: the action of sulphite on the S-S bridges of trypsin in the presence of *p*-chloromercuribenzoate has shown that for many artificial as well as natural substrates (benzoyl-L-arginine-amide, *p*-toluenesulphonyl-L-arginine methylester, Hb), three out of the six S-S bridges are essential for enzymatic action<sup>3</sup>. The study of *p*-nitrophenacyl bromide as an inhibitor of insulin, ribonuclease, papain and  $\alpha$ -chymotrypsin led to the suggestion that in the conditions used the imidazole group of histidine (as was known to be the case with RNase) is involved.

Further investigations on papain (photo-oxidation of histidine and of tryptophan residues as well as the oxidation of the latter by *N*-bromosuccinimide at pH 5.0) have established that one of each of these residues was essential for papain. These investigations also led to establishing that a polymer of leucine could be obtained by incubating leucineamide with papain at pH 7 as well as with a spleen preparation apparently different from

known cathepsins. With papain, a mixture of leucineamide and phenylalanine methylester formed a mixed peptide of leucine and phenylalanine. The active site of papain involved in peptidase activity is apparently different from that which is active in splitting benzoyl-arginineamide as deduced from the amount of ammonia evolved in the presence of one or of both of these substrates and of the differences in the kinetics of inhibition of papain with *N*-bromosuccinimide with both substrates<sup>4,5</sup>. These various investigations have also led Du Yu-cang and Tsou Chen-lu<sup>6</sup> to propose an original spectrophotometric method for determining protein SH groups by the absorption at 420  $\mu$ m of the complex formed between these groups and 1,4-naphthoquinone.

*Organic synthesis of insulin.* The research in protein structure and function led to an efficient method (> 50 per cent recovery using a biological test) of regenerating active insulin from its A and B chains obtained by the quantitative splitting by Na<sub>2</sub>SO<sub>3</sub> of the three disulphide linkages in the absence of urea<sup>7-9</sup>. Molecular properties of the B chain were examined and it was shown by optical rotatory and viscosimetric measurements that there was a low helical content<sup>10</sup>. This property apparently favours linear polymerization of the molecule when its S-sulphonate derivative is left at room temperature and at pH 6-9. The polymerization was inhibited in solutions containing 30 per cent dioxane chloroethanol or formamide, as well as in 5 M urea. These results suggested that hydrophobic bonds were the main forces holding the monomers together<sup>11</sup>. Both polymer and monomer were examined with the electron microscope. These investigations showed the polymer to be of indefinite length and 50-60 Å in diameter (which is slightly smaller than fibrous insulin); it seems to be formed by the assembly of units 200 Å long which are visible during the 'induction' period of polymerization<sup>12,13</sup>.

Then, in collaboration with the Institute of Organic Chemistry and the University of Peking which started the synthesis of the A chain, the workers of the Institute of Biochemistry began the synthesis of various peptides of the B chain<sup>14</sup>. At present complete A and B chains have been obtained<sup>15</sup>, and because of the excellent yields obtained for the re-synthesis of both natural chains of insulin both chains combined to their natural counterpart gave active insulin molecules.

*Comparative chemical and physico-chemical study of several strains of tobacco mosaic virus.* Four strains of TMV have been compared by serological methods, electron microscopy, fingerprinting of the proteins, etc. These observations suggest a close genetic parentship between the various strains (identical terminal threonine) but a closer similarity between the YMV<sub>15</sub> and DDV strains. During these investigations, a method using chloroethanol to precipitate the RNA was suggested for obtaining pure virus proteins. The proteins and nucleic acids can be recombined to form active virus. The amino-acid composition and the C-terminal pentapeptide structure of YMV<sub>15</sub> suggest that it is a new strain of TMV<sup>16,17</sup>.

*Muscle proteins and muscle functions.* Work on the molecular properties of muscle proteins has been commenced by the Institute of Biochemistry of the Academia Sinica in Shanghai; examinations of muscle are also being carried out in the Institute of Physiology. The first group is investigating with the electron microscope a number of para-crystalline forms of tropomyosin and paramyosin from a variety of biological species: both proteins, on the

basis of electron microscopic periodicities, are quite different; however, when present in the same muscle, as in some molluscs, some genetic relationship between them may exist on account of the intraperiod fine spacings of 140 Å found for *Anodonta* tropomyosin (recalling the characteristic fine spacing of the paramyosin from the same origin, in contrast to the usual 200 Å found for tropomyosin)<sup>18</sup>. Tropomyosins of various origins were also examined immunologically and by fingerprinting, and some interesting evolutionary aspects of shark and ray proteins were obtained<sup>19,20</sup>.

*Effects of ionizing radiations on some physical chemical properties of bovine plasma albumin.* It was shown that the binding of <sup>35</sup>S-methionine by bovine plasma albumin was increased after radon irradiation, but that the viscosity of the solution as well as its specific rotation did not change at neutral pH; however, at pH < 5 the specific rotation was lowered—but it was increased at pH > 7. The antigenicity of the protein was also reduced<sup>21,22</sup>.

### The Respiratory System

Earlier work by Wang Tsing-ying *et al.*<sup>23</sup> led to the partial purification of succinic dehydrogenase and the establishment, independently of other workers, that succinic dehydrogenase was a metalloflavo-protein containing non-haematin iron. Wu Chin-yung and Tsou Chen-lu<sup>24</sup> demonstrated that succinic dehydrogenase was linked to the cytochrome *c* part of the chain through a common velocity-limiting factor with NADH dehydrogenase. These investigations led Tsou Chen-lu and Li Wen-chieh<sup>25</sup> to an examination of cytochrome *c* from mammalian heart muscle and from yeast (see also Li Wen-chieh and Tsou Chen-lu<sup>26</sup>). The flavine prosthetic group of purified succinic dehydrogenase was separated after trypsin and chymotrypsin digestion from the proteins, and fractionated by electrophoresis into four flavine derivatives containing various amounts of attached amino-acids. These are inactive in the D-amino-acid oxidase test and are therefore distinct from FAD<sup>27</sup>. These flavin-adenine peptides do not show changes of absorption maxima in alkaline or acid solutions like FMN and FAD; this is probably due to the peptide linked to the isoalloxazine ring. The nature of the peptide and type of bond to the isoalloxazine ring awaits further characterization<sup>28</sup>. Continuing this work on the respiratory chains, Wu Chin-yung compared the action of various inhibitors on choline and L- $\alpha$ -glycerophosphate oxidase, and he concluded that both systems contain an antimycin A or BAL sensitive step, whereas cytochrome *b* is concerned only with choline oxidase<sup>29</sup>.

Further work on the relationship between the succinic and NADH oxidase systems by Liu Lin, Du Yu-cang and Tsou Chen-lu gave no experimental support for the suggestion that endogenous cytochrome *c* was directly linked to the succinic oxidase-NADH oxidase chain through a phospholipid<sup>30</sup>.

In 1964 Ao Shih-jou and Chang Yu-tuan<sup>31</sup> examined the oxidation of succinate in function of the concentrations of 2,4-dinitrophenol. At low concentrations of DNP respiration of succinate is increased, while at higher concentrations, after a short stimulation, there is an inhibition which can be prevented by ATP, which also prevents the inhibition of respiration that is obtained with amytal or arsenate. This led the authors to postulate that some activation energy is required for succinate oxidation.

Results leading to similar conclusions have been obtained by Wu Chin-yung *et al.*<sup>32</sup>. Ling Chi-shui and Wu Chin-yung further showed that no inhibition of respiration by DNP is observed when succinate is oxidized with 2,6-dichlorophenolindophenol—showing that DNP does not inhibit at the dehydrogenase level. In addition to ATP, restoration of respiratory activity could also be obtained in the presence of substrates of the NADH-linked

dehydrogenases; it was suggested that this high energy intermediate might be formed by the reversed reaction of the succinate linked endogenic reduction of NAD<sup>+</sup> in the presence of DNP. This reaction was demonstrated by Wu Chin-yung and Ling Chi-shui using sub-mitochondrial preparations in the presence of ATP; this reduction was inhibited by amital, dicoumarol and DNP and was completely dependent of magnesium, manganese and probably another metal which can also be removed by EDTA<sup>33</sup>.

Comparing the competitive inhibition by aged haematin on various flavoprotein enzymes<sup>34</sup>, it was shown that the inhibitory effect of this compound depended on the acceptor system, and the similarity of response on succinate and NADH oxidation (heart muscle mitochondria) with that of choline (rat liver mitochondria) and of  $\alpha$ -L-glycerophosphate (rabbit skeletal mitochondria) led to the suggestion that the two last-mentioned were also flavoprotein enzymes.

Whole-body irradiation was found to induce mitochondrial swelling within 30 min–3 h; this effect was greater in the presence of Ca<sup>++</sup> or thyroxine, and it is concluded that structural damage to the mitochondria had been induced. However, respiration and oxidative phosphorylation, which had been somewhat inhibited, became normal again after 4 h.

*Microsomal oxidation of NADP.* The oxidation of NADP in rat liver microsomes and supernatant was examined, and the use of various inhibitors showed that cytochrome oxidase is not involved, but that elements of both cell fractions seemed to be necessary for full activity<sup>35</sup>.

*Photosynthesis.* In addition to electron spin resonance investigations on chloroplasts in the Biophysics Institute, Peking, Tsou Chen-lu, of the Institute of Biochemistry, Shanghai, has devised kinetic equations for photosynthesis based on the assumption of two limiting reactions when flashing light is used—one photochemical and one biochemical. The relation between flash yield and flash period predicted by this equation agrees with experimental results recorded in the literature. The equation can be simplified under certain conditions and permits the calculation of the rate constant for both the limiting reactions as well as the 'concentration' of the 'photosynthetic unit'<sup>36</sup>.

### Nucleic Acids

Interest has concentrated on amino-acid transfer RNA (sRNA)—chiefly in the Institute of the Chinese Academy of Medical Sciences, Peking, as well as in the Institute of Biochemistry of the Academia Sinica in Shanghai.

*Preparation.* A method of preparation of sRNA from phenol bacterial extracts and fractionation with ammonium sulphate has been devised by Wu Kuan-yun *et al.*<sup>37</sup> and the isolation of an sRNA preparation with high methionine accepting activity homogeneous by sedimentation and electrophoresis tests has been obtained.

*Structure.* The same group devised a spectrophotometric method for the base analysis of RNA applicable to 100- $\mu$ g quantities<sup>38</sup>. An examination of 1-fluoro-2,4-dinitrobenzene derivatives of sRNA has enabled Hu Ping-cheng *et al.* to show that the reagent was fixed on 5'-phosphoguanosine; this finding should facilitate the analysis of the pG end of the sRNA chain<sup>39</sup>.

A paper electrophoretic and chromatographic method has also been described to obtain 'fingerprints' of sRNA digests with pancreatic RNase<sup>40</sup>. Differences between yeast and silk gland sRNAs have been described by this method<sup>41</sup>.

*RNase degradation.* Liu Wang-i and Wang Tch-pao<sup>42</sup> have shown the requirement of the Mg<sup>2+</sup> (or Ca or Na) for the activity of an RNase from *E. coli* on sRNA, whereas Ni<sup>2+</sup> is inhibitory. sRNA is much less susceptible to the enzyme than 'heavy' RNA—probably on account of the greater secondary structure of the former.

**Deamination.** The same authors<sup>43</sup> showed that the secondary structure of sRNA was altered after deamination with hydroxylamine in spite of the fact that this treatment did not alter the extinction coefficient at 260 mμ or the ultracentrifuge sedimentation pattern. However, the deaminated sRNA became more susceptible to RNase because of the alteration of its secondary structure.

**Effects of ionizing radiations.** Irradiation of DNA *in vitro* showed a drop in viscosity and rise in optical density at 260 mμ, which increased on heating the solution, indicating that hidden damage involving only one strand had occurred and that the double helix became less stable at temperatures nearing the normal melting-point<sup>44</sup>. After irradiation *in vivo* (1,000 r.) the DNA extracted from the spleen and thymus showed a reduced hyperchromic effect at alkaline pH indicating that the secondary structure might also be affected *in vivo*<sup>45,46</sup>.

**Protein synthesis.** Work on protein synthesis is only starting, but the stimulation of glycine incorporation into *E. coli* sphaeroplast proteins by RNA and various nucleotides (especially uridylic acid) has been shown by Tung Lin and Mann<sup>47</sup>.

In a combined cytochemical and biochemical investigation, K. H. Lu and P. Y. Wang have shown that glycine incorporation into silk fibroin appears to be a cytoplasmic process. In this investigation, RNA activity is also examined with phosphorus-32 (ref. 48).

A simple method for organ cultures on filter paper strips as a support for flowing culture medium has been described by Chen Jui-ming and Chuh Teh-ho<sup>49</sup>. By this procedure organ rudiments can proceed with differentiation and remain cytologically normal for 10–16 days, and the procedure appears very suitable for the examination of organ interactions, hormone action and many other aspects concerning the regulation of protein metabolism.

Antibody synthesis in rabbit popliteal lymph node cells cultured *in vitro* after antigen injection into the foot pad has been obtained in suspension cultures. In these preliminary investigations, a 20–30 per cent increase of antibody was recently observed—but in some experiments there was as much as 400 per cent increase. This was not seen if 2,4-dinitrophenol was added to the culture medium, but there was no modification of activity by cortisone acetate or by the addition to the immunized cells obtained from non-immunized ganglia<sup>50</sup>.

## EVALUATION OF CHEMICAL DIETS AS NUTRITION FOR MAN-IN-SPACE

By DR. MILTON WINITZ, JACK GRAFF, NEIL GALLAGHER\*, ANTHONY NARKIN\* and DANIEL A. SEEDMAN

Life Sciences Laboratory, United Technology Center, Sunnyvale, California

INVESTIGATIONS at the U.S. National Institutes of Health have led to the development of water-soluble, chemical diets which were successfully used in quantitative nutritional investigations in which the more conventional semi-synthetic protein diets had hitherto proved neither suitable nor applicable<sup>1-6</sup>.

\* Work performed while employed at the California Medical Facility, Vacaville, California.

Such investigations were designed to exploit the high degree of flexibility possessed by completely chemical diets by virtue of their liquid nature and the fact that they are composed solely of highly purified and discrete chemical constituents, each of which may be added to, omitted from, or varied in the diet at will. Diets of this type are unique in that: (a) their essential and non-essential nitrogen is provided in the form of highly pure

Table 1. BASE DIET COMPOSITION

Amino-acids			
L-Lysine · HCl	3.58 g	Sodium L-aspartate	6.40 g
L-Leucine	3.83 g	L-Threonine	2.42 g
L-Isoleucine	2.42 g	L-Proline	10.33 g
L-Valine	2.67 g	Glycine	1.67 g
L-Phenylalanine	1.75 g	L-Serine	5.33 g
L-Arginine · HCl	2.58 g	L-Tyrosine ethyl ester · HCl	6.83 g
L-Histidine · HCl · H <sub>2</sub> O	1.58 g	L-Tryptophan	0.75 g
L-Methionine	1.75 g	L-Glutamine	9.07 g
L-Alanine	2.58 g	L-Cysteine ethyl ester · HCl	0.92 g
Water-soluble vitamins			
Thiamine · HCl	1.00 mg	α-Biotin	0.83 mg
Riboflavin	1.50 mg	Folic acid	1.67 mg
Pyridoxine · HCl	1.67 mg	Ascorbic acid	62.50 mg
Niacinamide	10.00 mg	Cyanocobalamin	1.67 µg
Inositol	0.83 mg	p-Aminobenzoic acid	416.56 mg
α-Calcium pantothenate	8.33 mg	Choline bitartrate	231.25 mg
Salts			
Potassium iodide	0.25 mg	Potassium hydroxide	3.97 g
Manganous acetate · 4H <sub>2</sub> O	18.30 mg	Magnesium oxide	0.38 g
Zinc benzoate	2.82 mg	Sodium chloride	4.77 g
Cupric acetate · H <sub>2</sub> O	2.50 mg	Ferrous gluconate	0.83 g
Cobaltous acetate · 4H <sub>2</sub> O	1.67 mg	Calcium chloride · 2H <sub>2</sub> O	2.44 g
Sodium glycerophosphate	5.23 g	Sodium benzoate	1.00 g
Ammonium molybdate · 4H <sub>2</sub> O	0.42 mg		
Carbohydrates			
Glucose	555.0 g	Glucono-δ-lactone	17.2 g
Fats and fat-soluble vitamins*			
Ethyl linoleate	2.0 g	α-Tocopherol acetate	57.29 mg
Vitamin A acetate	3.64 mg	Menadione	4.58 mg
Vitamin D	0.057 mg		

\* Provided daily in separate supplement.

L-amino-acids; (b) they are administered as single, crystal-clear solutions which are nutritionally complete in themselves.

In essence, the diets are composed of balanced (but varying) proportions of L-amino-acids, the required water-soluble and fat-soluble vitamins, the pertinent salts, glucose, and ethyl linoleate as the source of essential fat. As each of the separate components is purified prior to its incorporation into the diet, the exact chemical composition of the mixture is known. The dry ingredients are dissolved in distilled water to yield a solution of 50–75 per cent solids which is substantially sterile, has a nutritive value of 2–3 cal/ml. and possesses excellent storage stability. Use of these diets in long-term nutrition investigations, including those bearing on longevity, reproduction and lactation over several generations, and on pathological conditions of various kinds, demonstrated that they will support normal growth, life-span, and

reproduction in experimental rats. Further, clinical investigations with hospitalized patients revealed that complete chemical diets maintained body-weight, rapidly replenished protein stores lost during periods of nitrogen depletion, and produced no abnormalities of liver and kidney functions<sup>7</sup>; the absence of adverse complications suggested that suitably formulated chemical diets are practical, safe, and biologically effective.

In order to evaluate the adequacy of chemically defined diets as potential long-term sustenance for man-in-space, clinical investigation was carried out at the California Medical Facility, Vacaville, California. The experimental subjects were adult male inmates of the Facility. Selection of 24 healthy subjects, from a total of 160 volunteers, was made on the basis of past medical history and comprehensive physical, neurological, and psychiatric examinations. The subjects were 24–39 years of age, exhibited a range in weight of 135–208 lb., and represented a wide variety of body types. The experiments were made in a locked ward where the subjects were kept under constant medical surveillance. Scheduled daily physical examinations and twice-weekly psychological examinations were conducted with each subject, who was also expected to follow a daily activity schedule that included moderate physical exercise, and co-ordination and strength tests. Chemical diets in aqueous solution (Table 1) were provided at 4 intervals daily to each subject, who was permitted to ingest whatever amount of diet satisfied his subjectively determined need; ingestion of anything else, with the exception of distilled water which was provided freely, was prohibited. Dietary intakes of the individual subjects ranged from 2,100 to 3,700 calories daily. Of the original 24 subjects, 9 dropped out during the course of the investigation, all for other than medical reasons.

Results obtained over a 19-week experimental period revealed that chemical diets sufficed to maintain the subjects with no untoward physiological or psychological responses, and free of complications or effects of toxicity. Indeed, physical and psychological examinations revealed marked improvements in the physical status and psychological outlook of each of the subjects. Fasting blood, drawn prior to initiation of the investigation, weekly during the experimental period, and bi-weekly for a 3-month period after return of the subjects to institutional fare, revealed values within the normal range for all parameters tested (Table 2) and further attested to the

§ Standard deviation of averages.

¶ No pre-experiment values taken.

physical well-being of the subjects. It is of especial interest to note that faecal elimination in all individuals was strikingly reduced, as contrasted with that induced by natural diets; several of the subjects experienced smaller than normal bowel movements at regular intervals of 5-6 days. Another observation of interest was the progressive decrease of the total serum cholesterol-levels of all subjects from an average baseline value of 226 mg per cent to an average value of 151 mg per cent after 19 weeks on the chemical diet. This progressive decrease was interrupted only during a 3-week period (fifth-seventh week) when replacement of 25 weight per cent of the glucose component of the diet with an equal weight of sucrose was accompanied by a sharp rise in the serum cholesterol-levels of all the subjects; this latter observation is described elsewhere<sup>8</sup>.

A number of characteristics of chemical diets can serve to overcome some of the limitations inherent in alternative space-food sources now being evaluated. Among these characteristics are: (a) high nutritive efficacy in ultra-compact form—1 ft.<sup>3</sup> of the diet, as a 75 per cent solution in water, will provide a 154-lb. astronaut with all his required essential and non-essential nitrogen, salts, vitamins, and fats, in addition to his estimated requirement<sup>9</sup> of 2,830 calories per day, for a period of a month; (b) complete water solubility—provides advantages in the administration of the diets in liquid form under conditions which will not permit the use of solids; (c) low bulk—induces low faecal residues and mitigates the critical problem of disposal of solid wastes; (d) complete nutritive flexibility—allows alteration at will of the amino-acid ratios, carbohydrate content, and levels of all other components, thereby making it possible to tailor formulations to the specific dietary needs of the individual

astronaut; (e) complete digestibility—provides dietary components in most elemental form in the event of disturbances of the digestive system; (f) good storage stability either in the solid state or as aqueous solution.

The promising clinical results already obtained, together with the high degree of flexibility and nutritional adequacy which complete chemical diets afford, indicate that consideration should be given to them as potential man-in-space diets.

We thank Dr. W. C. Keating, superintendent, California Medical Facility, for his co-operation and generous allocation of space for this programme, Drs. R. E. Prout and E. P. South for clinical consultation, Mr. K. E. Haden for assistance as programme co-ordinator, and United Technology Center for affording the time and assistance.

This work was supported in part by the National Aeronautics and Space Administration under grants *NSG-285* and *NSG-510*.

## VOLCANIC ERUPTION ON RAOUL ISLAND, NOVEMBER 1964

By J. HEALY and E. F. LLOYD

Geological Survey

AND

C. J. BANWELL and DR. R. D. ADAMS

Geophysics Division, Department of Scientific and Industrial Research,  
New Zealand

**R**AOUL, or Sunday, Island lies about 700 miles north-east of Auckland, New Zealand. It is about 5 miles across and is the largest island of the Kermadec group (Fig. 1). The only settlement now on the Island is a meteorological station serviced by the New Zealand Department of Civil Aviation.

Since the Island was discovered by d'Entrecasteaux in 1793, several volcanic eruptions are known to have occurred. The first recorded eruption<sup>1</sup> took place on March 9, 1814, when Captain Barnes, of the ship *Stella*, reported the presence of dark clouds, flame and suffocating vapour issuing from the Island. Two months later he returned and found in Denham Bay an island of three miles circumference covered with coarse grit. This was in a place where two months previously he had made soundings of 40-45 fathoms. The water in the bay was hot near the island.

In 1847 and 1853 settlers in Denham Bay were temporarily frightened away from the Island by earthquakes, and in 1872 an eruption occurred<sup>2</sup> from Green Lake within the main crater. The lake boiled vigorously and sent up a column of 'fire', killing trees immediately around the crater. At the same time, an island was again thrown up in Denham Bay, the earlier one having in the meantime disappeared, either by subsidence or erosion. By 1877 all that remained of this island was a shoal, and in 1887 Wolverine Rock and a shoal were charted. Another

eruption appears to have taken place between 1872 and 1876, when Dr. Stockwell<sup>3</sup> reported bare mud and rocks covering a belt extending from Green Lake to near the site of the present Meteorological Station on the north coast of the Island. Debris extended eastwards in the crater to Blue Lake, killing vegetation.

Since 1957 the New Zealand Seismological Observatory has operated a Willmore seismograph near the Meteorological Station, and several swarms of earthquakes originating in the Kermadec area have been recorded. On November 10, 1964, a series of extremely local earthquakes with *S-P* intervals of 1-2 sec began about 4 p.m. (local time, 12 h ahead of U.T.). Several of these shocks were felt, and by 8 p.m. the frequency of recorded shocks had risen to more than 80 an hour. The level of background tremor increased until by November 12 individual shocks were hard to distinguish. Thereafter, both the level of background tremor and the number of recorded shocks decreased. The largest earthquake (magnitude 5.7) occurred at 9.58 a.m. on November 14. The frequency of recorded earthquakes during the disturbance is shown in Fig. 2.

The water in Denham Bay was discoloured for a mile from the shore on November 12. One of us (E. F. L.) reached Raoul on November 19 in H.M.N.Z.S. *Lachlan* and found discoloured water, bubbles of gas and fragments of pumice reaching the surface in Denham

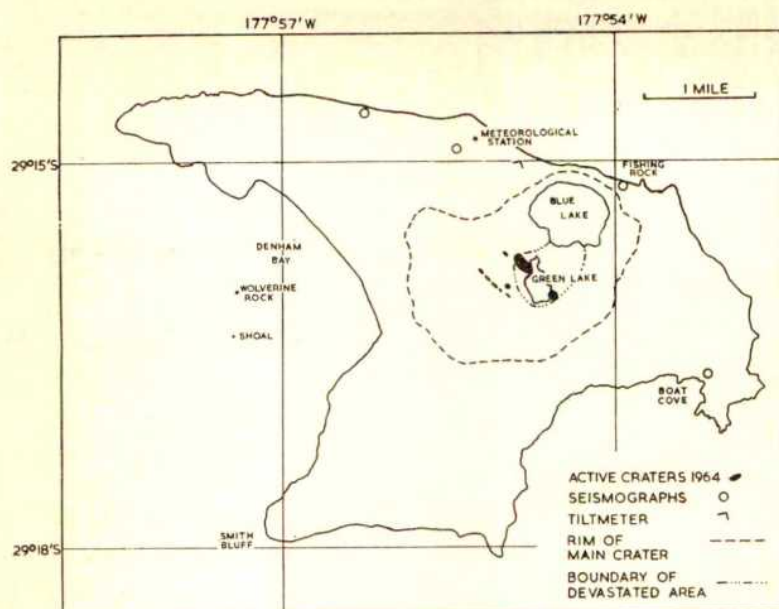

Fig. 1. Map of Raoul Island

Fig. 2. Frequency of local earthquakes recorded at main seismograph station

Bay. In the main crater, Green Lake was found to be discoloured, and whereas it had formerly been cold the temperature had reached an average of 30° C with local temperatures of 52° C. It was estimated that the lake had risen 20 ft. and was still rising half an inch per hour. A number of new hot springs had formed at the south-west end of the lake and the ground was observed to be heating up at a few places. *Lachlan* left on November 20.

At 5.56 a.m. on November 21 an eruption occurred in the main crater. Steam, mud and rocks were thrown to a height of 2,500 ft. for 3-4 min, then to lesser heights for a further half hour (Fig. 3). During the eruption the seismograph recorded a continual vibration 30-40 times the amplitude of the normal background level. On hearing of the eruption, *Lachlan* returned to the Island, arriving the same day, and a further inspection of the crater was made. An aerial inspection of the Island was made late on the afternoon of November 21 from an R.N.Z.A.F. aircraft and revealed that an actively steaming crater has been blasted out at the north-western end of Green Lake (Figs. 4 and 5). Steam was also rising from points at the south-eastern and south-western ends of the Lake. Low cloud obscured most of the main crater. From a vantage point on the Island the same afternoon it was noted that Green Lake had risen approximately 50 ft. and a stream of hot water was flowing north to Blue Lake. The vegetation along the northern and

western side of Green Lake had been destroyed, and a broad area of vegetation extending eastwards to Blue Lake was completely flattened and covered with grey mud and stones. Sporadic eruptions from these craters and other smaller ones to the west followed during the next two days. Blue Lake was found to be rising and becoming slightly warmer, and steam was rising from a number of points along the eastern shore.

On November 23 the Island was evacuated as a precaution.

A further aerial reconnaissance on November 30 (Fig. 5) showed that the volcanic activity had declined. It was also noticed that a thin covering of grey dust extended to Smith Bluff at the southern tip of the Island. A patch of discoloured water was again seen in Denham Bay. On December 6 *Lachlan* returned to Raoul carrying the meteorological party and a party of ten from the Department of Scientific and Industrial Research, including ourselves. Other members of the party were R. R. Dibble, G. E. K. Thompson and R. H. Orr (Geophysics Division), Dr. B. G. Weissberg and J. V.

Sarbutt (Chemistry Division) and E. J. Thornley (Information Service).

A more detailed examination showed small explosion craters aligned north-west-south-east along the western side of the main crater. Craters at the south-eastern and north-western ends of Green Lake and another small fissure crater farther to the north-west were similarly aligned. Between these lines is another small crater. The discharged material consisted entirely of country rock, and the explosive eruption is considered to have been phreatic in type. A number of samples were collected so that some of the previous eruptions on Raoul Island could be dated by the carbon-14 method.

Fig. 3. View of main eruption from Meteorological Station. (E. J. Thornley photo)

Fig. 4. Outflow from new crater on edge of Green Lake. (E. J. Thornley photo)

Fig. 5. Air view of Raoul Island crater looking south-west on November 30, 1964. Blue Lake at bottom right, Green Lake at centre with new crater pit on far shore, and other new crater pits at top left. Part of the devastated area is shown in foreground. (E. J. Thornley photo)

shocks were in the vicinity of Denham Bay probably at a depth of less than 6 km. The number of recorded shocks had decreased to between two and four per hour and remained at this level while the party was on the Island.

A two-component tiltmeter was installed on a level area near the north coast, at a point one mile north of the main eruption centre at the north-western end of Green Lake (Fig. 1). Recording commenced at about 4 p.m. on December 9, and will be continued by the station staff for a period of 2-3 months. The record obtained up to December 12 showed nearly continual irregular tilt movements with peak-to-peak amplitudes of about 1 sec of arc, and periods of 10-20 min. Movements were often of similar amplitude on both components, indicating tilting about a north-west-south-east axis, but one component (azimuth  $258\frac{1}{2}^\circ$ ) showed noticeably greater irregularity of movement over the whole period. A few sharp transient disturbances, amounting to several seconds of arc, and corresponding to rises in the direction of Green Lake, were recorded. Longer-term tilt movements were also observed amounting to several seconds of arc, but these appeared to be due to diurnal (possibly tidal) effects. No evidence was found of any progressive tilt movement in the period covered.

Further soundings were made in Denham Bay on December 12 from the motor launch *Acheron* (Lieutenant-Commander J. L. Harrison, R.N.Z.N.R.), and conditions were found to be rather similar to those observed in 1887 by Captain Fairchild. Bubbles and a few small pieces of pumice were seen rising to the surface over an area near the middle of the bay. Wolverine Rock could not be located at the position marked on the chart, but rock was found within four fathoms of the surface near where the previous shoal had been charted, and two holes of 30 and 17 fathoms were found where the depth was generally 13-14 fathoms.

On December 12, the scientific party left the Island in H.M.N.Z.S. *Lachlan*. The meteorological party remained and will continue the geological and geophysical observations.

The hot waters involved in the activity were strongly saline. The chloride concentration in the water issuing from the orifice of the main crater (flow rate 1-4 ft.<sup>3</sup>/sec at 95.5° C) was 8,280 p.p.m. on December 7, and water samples obtained from the large geyser hole on December 8 (temperature 87° C) contained 6,840 p.p.m. chloride.

Three additional seismographs were set up on the Island and ran for several days while the party was ashore. These showed that the centres of the larger

We wish to acknowledge the generous assistance of Commander W. J. Doole, R.N.Z.N., and the ship's company of H.M.N.Z.S. *Lachlan*; of the Department of Civil Aviation; and of Mr. C. Phillips and the members of his meteorological party, without whom the visit to the Island and the stay there would not have been possible.

## DEPARTMENT OF ZOOLOGY, UNIVERSITY OF GLASGOW

### INCREASED FACILITIES

MAJOR alterations within the Department of Zoology of the University of Glasgow together with the erection of buildings associated with it, namely, the new University Field Station on Loch Lomond and the Wellcome Laboratory for Experimental Parasitology, represent the extension and great improvement of its facilities for teaching and research. Alterations include provision of

a unit for electron microscopy completed last session together with the recent completion of new accommodation for investigations on animal behaviour, of an electrophysiological unit and of an experimental aquarium together with an insect hot-room for use in Agricultural Zoology.

The electron microscope, an E.M.6 instrument made by Associated Electrical Industries, was purchased out

Fig. 1. University Field Station, Loch Lomond. View from the south-west, showing main laboratory on the left, and dormitory block on upper storey on the right, with research laboratories below

of a grant of £14,608 from the Department of Scientific and Industrial Research and is housed in the basement in rooms constructed out of a former store-room. A preparation room (11 ft.  $\times$  22 ft.), which communicates with the corridor, contains a fume cupboard, coating unit, facilities for embedding procedures, and a small section set aside for the filing of negatives and prints. Provision is also made for writing and studying. An L.K.B. 'Knife-maker' is available for preparing glass knives. A microtome room (11 ft.  $\times$  9 ft.) opens off the preparation room and contains L.K.B., Porter-Blum and Huxley microtomes; there are also facilities for phase-contrast microscopy. An interesting feature of this room is the low bench height of 27 in. Normal sitting bench height is 29 in.-30 in., but, when sectioning, the worker is generally operating controls some 3 in.-4 in. above the bench top.

The entrance to the microscope room (11 ft.  $\times$  12 ft.) is guarded by a light-trap which, in order to save space, is constructed from a concertina-type partition. Apart from the microscope, the room contains only a steel storage cupboard and a small working bench.

The photographic rooms occupy the remainder of the space. The printing room (11 ft.  $\times$  14 ft.) has its own entrance to the corridor and is equipped with a 5 in.  $\times$  4 in. 'Omega' enlarger, a rotary print drier and a large stainless-steel sink unit. The small dark-room (11 ft.  $\times$  8 ft.), used for loading and developing plates, opens both into the printing room and microscope room. It is here that the power unit of the microscope is housed.

The entire unit, originally planned by Prof. G. Owen and Dr. H. F. Steedman, and for which Mr. J. B. Cowey is now responsible, is extremely compact and an attempt has been made to utilize efficiently all available space. Wherever possible, storage is provided by underbench units and glass-fronted wall cupboards. Doors are of the sliding type and, at the entrance to the printing room, the thickness of the original structural wall (in this case 2 ft.) has been used to provide a light-trap, a sliding door being placed on each side of the wall.

Also within former storage space in the basement a small laboratory has been constructed and equipped for research on mammalian behaviour by S. A. Barnett and his colleagues. A new experimental situation has been designed for investigation of interacting components of behaviour, such as eating and exploration. The connexion between choice of competing activities and learning ability is to be investigated. For this purpose, contrasting species, and also different genotypes within species, are to

be compared; and the effects of heterozygosis and of a 'stressful' (cold) environment are to be examined. New equipment, which allows detailed recording of an animal's movements over long periods, is to be used.

Establishment of the new Wellcome Laboratory for Experimental Parasitology having freed the one-storey animal house at the back of the Department, this has been completely reconstructed internally to provide two laboratories, two research rooms, a preparation room, insect hot-room and other facilities. These now constitute a Unit for research and teaching in comparative aspects of electrophysiology. When the Unit is fully operative (summer 1965), a co-ordinated research programme, involving investigations of synaptic transmission in insects, will be undertaken. The full complement of research staff will consist of up to five members, a lecturer, Dr. P. N. R. Usherwood, a research assistant, two graduate students and a technician.

The budget should be sufficient to provide each research worker with a complete set of apparatus for stimulation and for recording of bio-electric phenomena. The research assistant will devote some time to histological and electron-microscopical examinations of excitable tissue. The full complement of research apparatus for each research worker will consist of the following: (1) Oscilloscope, with plug-in units for recording versatility. (2) A pre-amplifier with neutralizing capacitance control for use with high-impedance microelectrodes. (3) An oscillograph camera, with or without pulsed frame charge. (4) Stimulator giving a programmed pulse output. (5) Stimulus isolation unit. (6) Micromanipulators for recording and stimulating electrode assemblies. (7) Palmer rackwork and stands. (8) 'Zoom' stereomicroscope for microdissection. (9) Facilities for simultaneous visual and photographic recordings of oscillograph traces, either by use of slave oscilloscope assembly or by use of a bio-electric reflexor unit. One of the Tektronix oscilloscopes will be modified by Dion Electronics Co., U.S.A., for use with a slave oscilloscope. This company will also be responsible for modifying some of the plug-in units of the 561 A oscilloscope to give 90° rotation of display. They will also be responsible for converting four Tektronix 'Type 161' pulse generators to give input selection for positive and negative pulse, positive and negative saw-tooth output, extended pulse duration output and d.c. output.

Teaching in the Unit will almost exclusively concern the fourth-year honours class, although a short elementary course designed as an introduction to electrophysiological

techniques will be given to the second-year class. It will be possible to provide facilities for as many as ten honours students. One main object of the teaching course will be to familiarize the students with basic research techniques in electrophysiology and also to give them opportunities for advanced studies on some of the excitable tissues or preparations which they will have previously studied.

Meanwhile a new University Field Station has been erected within the Queen Elizabeth Forest Park three miles south of Rowardennan on the east shores of Loch Lomond (Fig. 1). Constructed with the help of a substantial interest-free loan from the Nuffield Foundation, this replaces the two large wooden huts which formerly served this purpose on the opposite side of the loch. Planned by Messrs. Thomson, McRae and Sanders and built by the Weir Housing Corporation, the Station consists of three units: a main building, a caretaker's house and a boat-house. These are handsome buildings of unpainted red cedar vertical timbering on foundations of sanded brick and roofed with grey-green tiles, the whole blending well with the surrounding woodland. Laboratories are on a lower level and living quarters on an upper, each with its own entrance but with an intercommunicating stairway. Since it is highly desirable that the amenities of the area shall not be disturbed, the woodland has only been cleared to a distance of 40 ft. from the buildings and, especially when the trees are in leaf, they remain screened from view on all sides.

The Station is designed to house classes of up to eighteen students for periods of one or two weeks, but for most of the time it will be occupied by a limited number of research workers. On the upper floor the three dormitories descend in size to allow economical distribution of varying numbers of students of both sexes. The two smaller ones are fitted with benches so that either or both may have alternative use as laboratories. On this floor also are three single bedrooms, lavatories and bathrooms, drying rooms for field clothing, store-rooms, a well-appointed kitchen, and a common room which also serves as library and dining room.

On the lower floor there are two research laboratories and a large laboratory for both teaching and research. Again with flexibility in mind, fixed benches run only around the walls, leaving a clear floor space where chairs may be placed for lectures or folding tables set up for demonstrations and practical work.

The technician-caretaker's house stands to the west of the main building and the boat-house on the shore below it. The latter is of sufficient size to contain several rowing boats, all the ancillary equipment for the launch moored out in the bay before it, as well as seine nets and other collecting gear.

The Station depends on electricity for lighting, heating and power. Water is drawn from Loch Lomond and drainage discharged into the adjacent Dhu Lochan after treatment in a large septic tank followed by a percolating filter to safeguard this relatively small loch from pollution.

The work of the Field Station covers both fresh water and the land, animals and plants being investigated in their natural environment. Dr. H. D. Slack, who continues in general charge, directs aquatic research, which at present is particularly concerned with the distribution of animals on the profundal bed and with plankton populations. Terrestrial ecology is under the supervision of Dr. A. F. G. Dixon, and the present research involves three post-graduate students particularly concerned with population dynamics of sycamore aphids as a preliminary to an analysis of energy flow in woodland communities.

The situation of the Station, on the largest lake in Great Britain and one as yet little affected by human activities, gives scope for work which may have economic value. Its services have been offered for participation in the fresh water section of the International Biological Programme initiated by the International Council of Scientific Unions in 1961 with the view of exploring man's rapidly increasing demands on his natural environment.

The Wellcome Laboratories for Experimental Parasitology, erected following a gift of money by the Wellcome Trustees in 1963, are situated in the grounds of the Veterinary School at Garscube. They form a two-storey building containing some 9,000 sq. ft. of floor space, the ground floor being occupied by the Unit of Experimental Parasitology formerly housed in the Department of Zoology and of which it still forms an integral part. The new accommodation comprises three research rooms equipped respectively for isotopic, analytical and microscopic work; a sterile unit consisting of two transfer rooms, two incubation rooms, medium preparation laboratory and sterilizing room; an animal unit and aquarium; and five staff rooms. Under the direction of Dr. C. A. Hopkins, reader in experimental parasitology, there is an academic and research staff of six which it is hoped will increase to ten over the coming two years.

The Unit's main work is concerned with the development of pseudophyllidean tapeworms such as *Diphylobothrium* spp. and *Schistocephalus* spp. A primary objective is the development of techniques for the maintenance of these tapeworms throughout their life-cycle in the laboratory, a problem which involves *inter alia* the maintenance of copepod, piscine and avian hosts. Meanwhile, investigations using material obtained in the field are proceeding. These include the cultivation of larval *Schistocephalus solidus* in an attempt to reproduce *in vitro* under known conditions development that normally occurs in the perivisceral cavity of sticklebacks; an investigation of the changes that occur when a larval worm passes from the aerobic habitat of the fish coelom to the anaerobic habitat of the caecum of a duck; the cause of the close host specificity shown by the larva which is confined to a few, possibly a single, species of fish; an electron microscopic examination of the cestode cuticle with particular reference to site and method of food uptake; and an investigation of the factors which influence the longevity and death of the adult worm.

## OBITUARIES

### Prof. Josef Tomcsik

JOSEF TOMCSIK, who died in Basle on December 30, 1964, at the age of sixty-seven, was born of a Protestant family in Transylvania, when that country was part of the Austro-Hungarian Empire. Although he had adopted Swiss nationality for many years, he always regarded himself as Hungarian and suffered greatly at the distress of his country. Shortly before he died he visited Hungary, at the invitation of the present Government, for the first time since the War. This was unquestionably a great physical and emotional strain, coming, as it did, not long

after the death of his wife, Olga, who had acted always as his companion and confidential secretary.

As a young man, Prof. Tomcsik served in the First World War, in the Imperial Army, and saw action as a sniper. After the return of comparative peace to Hungary he took a degree in medicine and became an active research worker in bacteriology and immunology. His interests were wide, but he is especially well known for his work on the antigenic structure of the anthrax bacillus. He travelled extensively in Europe, America and the Far East, but continued to do his main work in Budapest, where he was elected professor when still in his twenties.

He was an exceedingly likable personality and made friends everywhere, but he especially enjoyed his stay of several years in Peking, where he acquired a taste for Chinese food and Chinese furnishings that was reflected in his town house in Basle in later years. He frequently spoke of his travels, and told with relish of his discomfort when unable to match the skill of his Chinese assistants in picking up glass beads with sterile glass rods, chopstick fashion. He was a remarkable linguist, speaking German, English and French almost perfectly. When reading a paper, in English, at the Institut Pasteur, he was asked a question in French, to which he replied in French. He then continued to deliver the paper in French until, after several minutes, he recalled himself and continued again in English. The notes from which he was speaking were probably in German, with annotations in Hungarian.

During the last War, Prof. Tomesik was invited to become director of the Institute of Hygiene at Basle. He foresaw the coming tragedy, and with much emotional conflict he accepted. Thereafter, for many years, return to his native country was barred to him.

The Institute is a fine, half-timbered house in the Petersplatz, and it was promptly christened Uncle Tom's Cabin by the medical students of the University of Basle. Here, for the second half of his active career, Prof. Tomesik settled down to teaching and research. He adopted Swiss nationality and built a country cottage of great charm, at Weggis on Lake Lucerne, backed by a steep chestnut forest of which he gradually acquired a considerable area, and of which he was exceedingly proud. Tragically, his imminent intention of retiring there was never fulfilled.

Returning to his study of the polysaccharides of *Bacillus anthracis*, Prof. Tomesik determined to employ the new technique of phase-contrast microscopy to the elucidation of antigen-antibody reactions, and thus half-accidentally discovered his method of visualization of antigenic components in the bacterial capsule, which renewed his fame at an age when many scientists find themselves slipping away from the bench to the desk. This was one of the big advances in cytological method that have been made in this century. The observation that an apparently formless capsule conceals an elaborate lamination of polysaccharide and polypeptide layers is in itself an important and remarkable one. The full potentialities of the technique, applicable as it is to any biological material, has

not so far been realized, for the lack, perhaps, of others with his skill and patience to prepare antisera from antigenic fractions and apply them to the microscopic field. Perhaps, in the memory of a good and kind man, and a fine scientist, one of the institutions of the world will establish a grant to enable his work to be employed and extended as it deserves to be. He lived for his science and died in harness; he would ask no better memorial.

K. A. BISSET

### Prof. H. den Hartog

HENDRIK DEN HARTOG, professor of biophysics in the University of Amsterdam, died on July 15, 1964, at the age of forty-eight.

Den Hartog, whose early scientific research was concerned with cosmic ray physics, developed a lively interest in the ultimate performance of Geiger-Müller counters, which grew to encompass the fundamental limitations of measuring instruments in general. One of his many contributions to this field, in collaboration with F. A. Müller, is the now classic treatment of "Optimum Instrument Response for Discrimination Against Spontaneous Fluctuations", published in 1947. His originality and skill in the application of the principles of physical measurements are seen in a wide spectrum of instruments for use in fields as diverse as biochemistry and non-destructive materials testing.

In later years den Hartog directed his efforts toward problems of biology, especially sensory phenomena. Although his accomplishments in this field were many, he was not to witness the fruition of his more recent ideas on the investigation of biophysical phenomena. Appointed to the newly created chair in biophysics in the University of Amsterdam in the autumn of 1962, he became ill just as the toils of organizing a department and moving into a new laboratory were ending.

Den Hartog gave generously of his time to help others. His advice was as well considered as his own actions, and often unmasked hidden facets of brilliance. In this age of specialization when most persons are impatient for success, and change is often mistaken for progress, den Hartog was a rare man. He pursued a broad range of intellectual activities and considered no endeavour to be complete until the product was as close to perfection as human skills allow.

A. S. BRILL  
B. CHANCE

## NEWS and VIEWS

### Chairman of Natural Environment Research Council

SIR GRAHAM SUTTON has been appointed chairman of the new Natural Environment Research Council which will be set up by Royal Charter, in accordance with the Science and Technology Bill now before Parliament. The major part of Sir Graham Sutton's time will continue to be devoted to his responsibilities as director general of the Meteorological Office. The Natural Environment Research Council's functions, defined in broad terms in the Science and Technology Bill, are to support and carry out research in the Earth sciences and ecology (in particular, geology, meteorology, seismology, geomagnetism, hydrology, oceanography, forestry, nature conservation, fisheries, and marine and freshwater biology); to disseminate knowledge in these subjects; and to establish, maintain and manage nature reserves. The Research Council will take over the Nature Conservancy, the Geological Survey and Museum, the Hydrology Research Unit, the National Institute of Oceanography and the responsibilities hitherto undertaken by the Development Commission in relation to marine and freshwater biology and fishery research.

### Sir Graham Sutton, C.B.E., F.R.S.

SIR GRAHAM SUTTON has been director-general of the Meteorological Office since 1953, and a Fellow of the Royal Society since 1949. Born in 1903, Sir Graham Sutton was educated at Pontywarn Grammar School, and as a Scholar, at the University College of Wales in Aberystwyth and at Jesus College, Oxford. He was a lecturer at the former College from 1926 until 1928, and was made an Honorary Fellow there in 1958. From 1928 until 1941 he served in the Meteorological Office. During the War, Sir Graham Sutton acted as superintendent of research in the Chemical Defence Experimental Establishment at Porton, and as superintendent of Tank Armament Research. From 1945 until 1947 he was chief superintendent at the Royal Radar Research and Development Establishment at Malvern. In 1947 he was appointed Bashforth professor of mathematical physics at the Royal Military College of Science, and later dean at the same College. From 1950 until 1955 he was chairman of the Atmospheric Pollution Research Committee, and in 1951 he became scientific adviser to the Army Council. In the past he has served as president of the Royal Meteor-

ological Society and the Institution of Professional Civil Servants. Sir Graham Sutton was made a Commander of the Order of the British Empire in 1950 and a Knight Bachelor in 1955. Since then, Sir Graham has been a member of the Nature Conservancy, of the Executive Committee of the World Meteorological Organization and of the Council of the University College of Wales, Aberystwyth.

**Deputy Director of the General Post Office Research Station:** Dr. J. R. Tillman

DR. J. R. TILLMAN has been appointed deputy director of research of the Post Office Research Station, Dollis Hill, London, N.W.2. Born at Gillingham, Kent, in 1912, Dr. Tillman was educated at Gillingham Grammar School. While at the Imperial College of Science and Technology, he obtained an honours B.Sc. degree and a Ph.D. for research in electron diffraction. He was a Beit Research Fellow during 1934-36, and with P. B. Moon discovered the thermal neutron and the selective absorption of slow neutrons. His other academic qualifications include D.Sc. He is also a Fellow of the Physical Society, an Associate of the Royal College of Science, and an Associate Member of the Institution of Electrical Engineers. He joined the Post Office Research Station in 1936, becoming a principal scientific officer ten years later and a senior principal scientific officer in 1952. His work at the Station includes the design of receivers for the first international dialling installations and for the national system, and he carried out a detailed study of high-speed time division multiplex switches for electronic exchanges. During the 1950's he became an acknowledged expert on transistors, and his Division at the Station specialized in their long-term reliability for telecommunications applications, particularly submerged repeaters for under-sea telephone cables. He is joint author of a book *Theory and Practice of the Transistor*. Another of his activities is concerned with organizing the recruitment of graduates for work at the Station.

**Honorary Fellowship of the International Institute for Conservation of Historic and Artistic Works:**

F. I. G. Rawlins, C.B.E.

At a luncheon party in the Athenaeum Club on February 9, 1965, Mr. F. I. G. Rawlins was presented with a special issue of *Studies in Conservation*, marking his recent election to an Honorary Fellowship of the International Institute for Conservation of Historic and Artistic Works (IIC). IIC, which now includes in its membership a majority of the professional conservators throughout the world, owes a great deal to Mr. Rawlins. His contribution has two distinct aspects, represented, respectively, by his work as first secretary-general of the Institute (1950-58) and by his honorary editorship of the Institute's journal, *Studies in Conservation*, from 1952 until 1958. During this period, Mr. Rawlins was scientific adviser to the Trustees of the National Gallery, London. As secretary-general he gained and held the interest and support of those most prominent in the profession in Europe and America as well as in countries as far away as India and Japan, and provided a firm foundation for the later development of the Institute. As editor of *Studies in Conservation* he set an exacting standard of scholarship and scientific precision. Among those contributing to the special issue of the journal are the following present and past officials of the Institute: Dr. Arthur van Schendel, director of the Rijksmuseum, Amsterdam; Dr. Harold Plenderleith, director of the International Centre for the Study of the Preservation and the Restoration of Cultural Property, Rome; Mr. George Stout, who represents pioneering efforts in the United States; Dr. A. E. Werner, keeper of the British Museum Research Laboratory; Mr. N. S. Brommelle, who succeeded Mr. Rawlins as secretary-general and is

keeper of the Conservation Department at the Victoria and Albert Museum; and Mr. Garry Thomson, the present editor of *Studies in Conservation* and scientific adviser to the Trustees of the National Gallery, London.

**Director of An Foras Taluntais**

THE Council of An Foras Taluntais has, in accordance with the terms of the Agriculture (An Foras Taluntais) Act, 1958, appointed Dr. T. Walsh to the post of director of An Foras Taluntais (The Agricultural Institute) on a permanent basis, as from August 1, 1965. On the establishment of An Foras Taluntais in 1958 the Government appointed Dr. Walsh as the first director for a period of seven years as from August of that year (see *Nature*, 184, 28; 1959). This term of office expires on July 31 next.

**The U.S. National Science Foundation**

DR. L. J. HAWORTH, director of the National Science Foundation, has announced a major reorganization of the activities of the Foundation in support of science education. Three divisions have been established under the associate director for education, Dr. H. W. Riesen. These divisions, which correspond to educational levels, are: the Division of Pre-College Education in Science, headed by Dr. K. Kelson, formerly deputy director of the Division of Scientific Personnel and Education, which has now been abolished; the Division of Undergraduate Education in Science, headed by Dr. L. Shanor, formerly head of the undergraduate education in the Sciences Section; and the Division of Graduate Education in Science, headed by Dr. R. D. Fontaine, formerly in charge of the Fellowships Section.

**The Royal Society of London**

THE annual report of the Council of the Royal Society for the year ended September 30, 1964, confirming the earlier announcement that Nos. 6-9 Carlton House Terrace are to be converted to provide adequate and dignified accommodation for the Society under a 99-year lease now being negotiated with the Crown Estate Commissioners, expresses the hope that reconstruction will commence early in 1965 (Pp. 74. London: The Royal Society, 1964). The second expedition to North Borneo spent four months in the Pinosuk Plateau region of Mount Kinabalu, Sabah, Malaysia, in January-May 1964. Planning continues on the expedition which is to be sent to the Solomon Isles in 1965. A small expedition investigated the volcanic areas near the coast of the Aden Protectorate, and another small expedition carried out volcanological and petrological investigation on Ascension Island in June 1964. A committee appointed in October 1963 has become a joint committee with increased representation from the Department of Scientific and Industrial Research and authority to deal with both technical and financial implications of the proposal for a large telescope in the southern hemisphere. At the conference of scientific editors held in April 1964, a further conference was arranged for November, and the Council has also arranged a further meeting of officers of British scientific societies to discuss such matters as office and meeting accommodation and the need for an international conference centre in London. A Developing Countries Sub-committee of the International Relations Committee was set up in June 1964 to advise the latter Committee on action which the Society might take to assist scientific and technological research in developing countries, and on matters concerning the developing countries in the activities of the International Council of Scientific Unions. One hundred research projects are now being administered by the Scientific Research in Schools Committee, the report (pp. 16) to the Council of which is included with the Council's annual report. There is some reference to United Kingdom co-operation in international space research. Parliamentary grants administered by the

Royal Society for the fiscal year 1964-65 totalled £251,000 compared with £220,000 in 1963-64, of which £100,000 were for scientific investigations, £45,600 for research professorships, and £95,400 for international research and scientific congresses. Brief report on researches are appended, including lists of publications, from the research professors and Research Fellows.

### European Launcher Development Organization

IN a written answer in the House of Commons on February 3, the Minister of Aviation, Mr. R. Jenkins, stated that a conference, attended by all the Member States of the European Launcher Development Organization, met in Paris during January 19-21, to review the activities of the organization and to examine proposals for its future work. The cost of completing the first programmed launcher, based on conventional techniques and with a limited operating capacity, would be higher than the original estimate, and a working group had been set up to consider the feasibility of using the technical results already achieved and the experience acquired by the Organization to develop an advanced launching system making use of the most modern techniques. The system would continue to use *Blue Streak* as the first stage, and the Conference would be convened again later this year to review progress. Britain's part in the European Space Research Organization was the responsibility of the Secretary of State for Education and Science.

### Science Research Council

IN a written reply to a question in the House of Commons on February 4, Mr. A. Crosland, the Secretary of State for Education and Science, announced that a Science Research Council would be constituted after the enactment of the Science and Technology Bill which is now before Parliament. The Council, under Sir Harry Melville's chairmanship, would consist of: Lord Halsbury; Dr. A. Caress, director of research, Imperial Chemical Industries, Ltd.; Dr. D. G. Christopherson, vice-chancellor and warden of the University of Durham; Dr. S. C. Curran, vice-chancellor of the University of Strathclyde, Glasgow; Prof. G. C. Drew, professor of psychology in University College, London; Prof. M. R. Gavin, professor of electronic engineering in University College of North Wales, Bangor; Sir Ewart Jones, Waynflete professor of chemistry in the University of Oxford; Sir Bernard Lovell, professor of radio astronomy in the University of Manchester and director of Jodrell Bank Experimental Station; Prof. K. Mather, professor of genetics in the University of Birmingham and vice-chancellor-elect of the University of Southampton; Prof. C. F. Powell, Henry Overton Wills professor of physics in the University of Bristol; Prof. J. E. Smith, professor of zoology in Queen Mary College, University of London, and director-elect of Marine Laboratory, Plymouth.

### Committee on Manpower Resources for Science and Technology

IN reply to a question by Mr. J. Tinn in the House of Commons on February 4 concerning the arrangements for the continuation of the work formerly performed by the Committee on Scientific Manpower, Mr. A. Crosland stated that the Committee would be known as the Committee on Manpower Resources for Science and Technology. The Committee had now been re-appointed and the members were: Sir Willis Jackson, professor of electrical engineering, Imperial College of Science and Technology (chairman); Sir Leon Bagrit, chairman and managing director, Elliot-Automation, Ltd.; Prof. J. G. Ball, professor of physical metallurgy, Imperial College of Science and Technology; Mr. G. S. Bosworth, director of Group Personnel Services, the English Electric Company, Ltd.; Mr. S. L. Bragg, chief scientist in the Aero Engine Division of Rolls Royce, Ltd.; Dr. E. F. Brookman, managing director of the Paints Division, Imperial

Chemical Industries, Ltd.; Lord Brown of Machrihamish, chairman of the Glacier Metal Co., Ltd.; Dr. S. G. Hooker, technical director (Aero) of Bristol Siddeley Engines, Ltd.; Dr. F. E. Jones, managing director of Mullard, Ltd.; Prof. C. A. Moser, professor of social statistics, School of Economics and Political Science in the University of London; Prof. L. Rosenhead, professor of applied mathematics in the University of Liverpool; Prof. J. R. N. Stone, Leak professor of finance and accounting in the University of Cambridge; Sir Peter Venables, principal of the College of Advanced Technology, Birmingham; Mr. L. T. Wright, general secretary of the Amalgamated Weavers Association. Members from Government Departments: Mr. H. E. Bishop, Central Statistical Office; Mr. G. B. Blaker, Department of Education and Science; Mr. R. H. W. Bullock, Ministry of Technology; Mr. R. C. Griffiths, University Grants Committee; Mr. F. Jones, Ministry of Economic Affairs; Mr. F. Pickford, Ministry of Labour; Mr. W. G. Pottinger, Scottish Office; Mr. J. K. Thompson, Ministry of Overseas Development. The Committee would report its findings to the Secretary of State for Education and Science, and the Minister of Technology.

### Grants to Universities and Colleges in Britain

IN a written answer in the House of Commons on February 1, Mr. A. Crosland stated that since the settlement of the grants in aid of the recurrent expenditure of universities and colleges in Britain for the last three years of the quinquennium ending on July 31, 1967, was adjusted in February 1964 to take account of the acceptance of the Robbins Committee's proposals for immediate expansion, supplementary grants had been approved for the increases in academic salaries approved on the recommendation of the National Incomes Commission and for a further increase in the intake of medical students. The present level of grants had been reviewed following advice from the University Grants Committee, and, to assist the universities to meet the objectives of the Robbins Report, in view of increased costs since 1963, the grants for these three academic years would be increased by £5.8 million, bringing the total estimated recurrent provision, excluding rates, to £86.3 million in 1964-65; £99.3 million in 1965-66; and £109.8 million in 1966-67, or about £295 million in all.

### The University of Aston in Birmingham

THE College of Advanced Technology, Birmingham, which is shortly to submit a petition to the Queen in Council for the grant of a Charter as a new technological University, has agreed to request that the title of the new University be "The University of Aston in Birmingham". The matter of an appropriate title has been under discussion for some time, and the title now suggested has been agreed on by the Governing Body of the College after considering many views, including the results of questionnaires to members of staff. The College grew up in the City of Birmingham, and was run by the Corporation for many years until 1962, when an independent Governing Body was set up. The name now suggested will carry with it something of the history of the institution, and also reflects the fact that it is the intention of those responsible for the new University that it should remain on its present site near the centre of the City. It has already been announced that the Chancellor-designate of the new University is Lord Nelson of Stafford. The first Pro-Chancellor will be Mr. J. A. Hunt, chairman of the Board of Governors of the College, who for many years has been connected with further education, and education for commerce and industry. Mr. Hunt is director and general manager of the Hymatic Engineering Co., Ltd., in Redditch, and a director of other companies, as well as a member of many regional and national bodies connected with education, commerce and manage-

ment, including the Central Training Council, the National Advisory Council on Education for Commerce and Industry and the Redditch New Town Development Corporation. The first Vice-Chancellor will be Sir Peter Venables, at present the Principal of the College. Sir Peter has been Principal since 1956. The draft for the Charter of the new University has been submitted to the University Grants Committee for comment; it is anticipated that the petition for the Royal Charter incorporating the new University will shortly be submitted to the Privy Council, and it is hoped that the Charter may be granted before the beginning of the next academic session in October 1965.

#### Economics and Statistics Committee formed by the Scientific Instrument Manufacturers' Association

THE Scientific Instrument Manufacturers' Association has set up an Economics and Statistics Committee to meet the needs of the Association and its members. This Committee will co-operate closely with other bodies doing similar work. The importance of statistical and economic information has become increasingly recognized over the past few years. Government departments and the National Economic Development Council require fuller information in their task of formulating plans, and the demand from companies for data to assist in market research and to assess their own position has greatly increased. Basically two types of information are sought: accurate and detailed data extending back over a reasonable period of time on sales, exports, imports; and secondly, an assessment of trends within the industry and forecasts of future trends. The Economics and Statistics Committee will act as an advisory body to the Council of the Association for the provision of economic and statistical information. It will determine the information likely to be of value to the industry, advise on its collection, analysis and dissemination, and consider methods of improving it. Another aspect of the work of the Committee will be the formulation of terms and definitions for use in the statistics work of the Association. The Committee is composed of members representing each of the sections of the instrument industry and is under the chairmanship of Mr. H. C. Pritchard (Cambridge Instrument Co., Ltd.).

#### The Confederation of British Industry

THE Integration Committee appointed to supervise the establishment of a national industrial organization by the amalgamation of the National Association of British Manufacturers, the Federation of British Industries and the British Employers' Confederation has announced that a revised Charter (on the lines of the outline plan already circulated to members) is in the course of preparation, and it is expected that meetings of members of the three bodies concerned will be held on March 24 at which the integration agreement will be presented for approval.

On this basis the Integration Committee proposes that, to take effect as soon after the meetings as practicable (the anticipated effective date being early in August): (a) the name of the new organization shall be the Confederation of British Industry (C.B.I.); (b) the first president of the C.B.I. shall be Mr. M. Laing; (c) the first vice-presidents of the C.B.I. shall be Sir Peter Runge and Mr. L. Jenkins; (d) the office of deputy president shall be created, but no immediate appointment to this office is proposed; (e) the first director-general of the C.B.I. shall be Mr. J. Davies, at present vice-chairman and a managing director of Shell Mex and B.P., Ltd., who will take up his post on the effective date; (f) Mr. P. F. D. Tennant, at present deputy director-general of the Federation of British Industries, shall be relieved of general duties during the formative period of the C.B.I. in order to give special assistance to the director-general;

(g) appointments to the posts of deputy director-general of the C.B.I. shall be made by the director-general in consultation with the president in due course; (h) Mr. H. J. Gray will continue as director of the National Association of British Manufacturers until the effective date, when he shall be appointed director of regions in the C.B.I.; (i) Mr. D. Taylor, at present deputy director of the British Employers' Confederation, shall be appointed director of labour and social affairs in the C.B.I.; (j) Sir Norman Kipping will continue as director-general of the Federation of British Industries until the effective date and thereafter will be available to the C.B.I. on a part-time basis for consultation until his normal retirement date on May 11, 1966; (k) Sir George Pollock will resign his post as director of the British Employers' Confederation with effect from June 30. Mr. D. Taylor, the present deputy director, will assume the position of acting director of the body from July 1 until the effective date. Sir George will be available to the C.B.I. on a part-time basis for consultation and will also represent the C.B.I. at the International Labour Organization.

If the proposals for a revised Charter are accepted, a formal petition will be submitted to Her Majesty in Council, requesting the grant of a Supplemental Charter.

#### Laboratory Animals

A DIRECTORY of sources of laboratory animals, and of suppliers of equipment and materials connected with their maintenance, is prepared by the Institute of Laboratory Animal Resources. The fifth edition is now available (*Laboratory Animals. II, Animals for Research*. Publication 1199. Pp. 89. Washington, D.C.: National Academy of Sciences-National Research Council, 1964. 2 dollars). The directory comprises five sections: Section I lists the common mammalian and avian laboratory species, giving the strain designation and the breeding system; Section II lists the species of animals "obtained from Nature" and available through commercial suppliers; and Section III lists feedstuffs, cages and other equipment. Each item in these sections is referred to by a code number, and the fourth section of the booklet provides a guide to the manufacturer and suppliers of the animals and equipment coded in the first three sections. In the final section the animals are indexed by taxonomic and vernacular names.

#### Soils and Land-use in Buckinghamshire

A RECENTLY published memoir of the Soil Survey of Great Britain by B. W. Avery describes the soils and features of the region mapped on Sheet 238 (*The Soils and Land Use of the District around Aylesbury and Hemel Hempstead*. Pp. vii+216+11 plates. London: H.M.S.O., 1964. 35s. net). The total area amounts to 216 square miles, of which about two-thirds comprise part of the Chiltern plateau of Chalk upland, which falls in a south-easterly direction down to 400 ft. from an indented scarp north-east-south-west and rising to 800 ft. The 'Icknield Belt' lies between the escarpment and the Vale of Aylesbury to the north-west, which is mainly on Gault and Kimmeridge clays. This memoir is the first to give a detailed account of soils overlying Cretaceous rocks and associated superficial deposits. The first chapter concerns the geology, physiography and climate of the area and discusses local fluctuations from the average daily maximum and minimum temperatures of 55° and 42° F and the reasons for an average summer soil moisture deficit of about 4 in. More than half the volume is devoted to a discussion of soil formation processes and survey methods—there is a useful appendix defining the terms used in profile description—and to the classification of calcareous, brown earth, podzol and gley groups of soils, with details of representatives of various series. There is a chapter on land-use capability and requirements for which much valuable information has been derived from

the long-term experiments on Rothamsted soils that are typical of much of the area. There is also a chapter by J. M. B. Brown on the recent history of the woodlands, describing their exploitation for fuel and wood-working industries with changes in management according to economic and social demands. Beech is still the principal species, especially on well-drained soils of high base status, but in some places the conditions favour oak. There is a list of references to appropriate publications and a subject index.

### Standards of Radioactivity

THE National Physical Laboratory has added sodium-22, chromium-51, manganese-54, cobalt-57 and sulphur-35 to the list of standards of radioactivity issued by the Laboratory. During 1965 standards will be made available as follows:

Potassium-42	February	Phosphorus-32	June
Sodium-22	March	Cobalt-57	September
Manganese-54	April	Iron-59	October
Chromium-51	May	Sulphur-35	November

Standards are available from stock of strontium-90 in equilibrium with yttrium-90. Application forms for all these standards can be obtained from the Applied Physics Division of the National Physical Laboratory, Teddington, Middlesex. Intercomparisons, held during the past two years, of standards of cobalt-60 and sodium-24 issued both by the National Physical Laboratory and by the Radiochemical Centre, Amersham, have been in satisfactory agreement. Therefore, in line with the general policy of the National Physical Laboratory to transfer routine standardization to commercial organizations, cobalt-60 and sodium-24 will now be available only from the Radiochemical Centre, in a similar manner to gold-198 and iodine-131. Ultimate responsibility for primary standardization is with the National Physical Laboratory, and issues of nuclides which have been transferred to the Radiochemical Centre as outlined here will also be measured by the Laboratory.

### Organization for Economic Co-operation and Development Fellowships

THE Organization for Economic Co-operation and Development is offering a limited number of fellowship grants in the field of human resource development planning. Award winners will spend a year, from approximately July 1, in training, research and planning, within the framework of national planning teams engaged on specific projects sponsored by the Organization and member countries. Applicants should be qualified university graduates under thirty-five, with degrees in economics or other appropriate disciplines. Professional or postgraduate experience is a prerequisite, and candidates must be able to work in either English or French. Applications should be made before March 1. Further information can be obtained from the Directorate for Scientific Affairs (Fellowships), Organization for Economic Co-operation and Development, 2 rue André-Pascal, Paris 16.

### The Night Sky in March

NEW Moon occurs on Mar. 3d 10h U.T. and full Moon on Mar. 17d 11h. The following conjunctions with the Moon occur: Mar. 8d 15h, Jupiter 2° N.; Mar. 16d 17h, Mars 1° S. Mercury sets at 18h 00m, 19h 50m, 19h 50m on Mar. 1, 16 and 31 respectively. Venus is too near the Sun for observation. Mars makes its nearest approach to the Earth on Mar. 12d 01h; Mars is above the horizon all night during the month; its stellar magnitude is -0.9; its distance from the Earth on Mar. 12 is 62 million miles and during the month retrogrades through Virgo towards Leo. Jupiter sets at 0h 10m, 23h 25m, 22h 40m at the beginning, middle and end of the month respectively;

its stellar magnitude is -1.8; its distance from the Earth on Mar. 15 is 510 million miles and during the month advances into Taurus. Saturn is unfavourably placed for observation during the month. There is one occultation of a star brighter than magnitude 6 observation being made at Greenwich: Mar. 14d 01h 14.9m,  $\gamma$ Cnc (D). D refers to disappearance. The spring equinox occurs on Mar. 20d 20h.

### Announcements

DR. CASIMIR FUNK has been awarded the Carl Neuberg Medal for 1964, in recognition of his work on vitamin research in the United States.

DR. I. GIAEVER of the General Electric Research Laboratory, in Schenectady, New York, has been awarded the 1965 Oliver E. Buckley Solid State Physics Prize of the American Physical Society, for his discovery that electrons can tunnel through a simple insulating layer only 10-100 atoms thick between two thin films.

DR. P. LIMBERG, formerly lecturer at the Institute for Plant Breeding and Plant Genetics of the University of Giessen, has been appointed director of the Institute for Plant Breeding and Seed Research of the Agricultural Research Centre, Braunschweig-Völkenrode, in succession to Prof. O. Fischnich, who is now assistant director-general of the Food and Agriculture Organization in Rome.

THE British Federation of University Women, Ltd., offers a prize of £15 to women undergraduates for an essay on one of the following subjects: the responsibility of the artist in the modern world; the responsibility of the scientist in the modern world; the student abroad. The closing date for the competition is March 16. Further information can be obtained from the Secretary, British Federation of University Women, Ltd., Crosby Hall, Cheyne Walk, London, S.W.3.

A SYMPOSIUM on "Comparative Phytochemistry", organized by the Phytochemical Group, will be held in Cambridge during March 30-April 1. Further information can be obtained from A. H. Williams, Research Station, Long Ashton, Bristol.

A SPRING meeting on "Adsorption of Silver Halide Surfaces", arranged by the Scientific and Technical Group of the Royal Photographic Society, will be held in the University of Bristol during March 31-April 1. Further information can be obtained from Mr. R. Cox, Ilford, Ltd., Ilford, Essex.

THE Laboratory Apparatus and Materials Exhibition, sponsored by the Scientific Instrument Manufacturers' Association of Great Britain, will be held at Earls Court, London, during March 29-April 2. Further information can be obtained from the Press Officer, U.T.P. Exhibitions, Ltd., Racquet Court, Fleet Street, London, E.C.4.

A CONFERENCE for headmasters and headmistresses on "The Challenge of Modern Engineering", arranged by the Royal Society and the Engineering Institutions Joint Council, will be held in Churchill College, Cambridge, on March 30. Further information can be obtained from R. W. J. Keay, The Royal Society, Burlington House, London, W.1.

A SYMPOSIUM entitled "From Mendel's Factors to the Genetic Code", sponsored jointly by the Royal Society and the Genetical Society of Great Britain, will be held in University College, London, during March 10-13. The programme will include sessions on: the gene, its structure, function and control; chromosomes and genes; genetics of man; quantitative and population genetics. Further information can be obtained from Prof. D. Lewis, Department of Botany, University College, Gower Street, London, W.C.1.

## THE BRITISH COUNCIL

AN article describing the opportunities which the British Council provides for a career overseas accompanies the customary review of the year in the annual report for 1963-64\*. It is of particular interest to the scientist. The staff of the Council considered in this article now numbers about 500; most of them are overseas for about four-fifths of their service, and some 80 per cent of them work in developing countries and are directly or indirectly concerned in education. The total staff of the Council numbers 3,700, of whom 1,600 serve in London and some twenty other universities. Of the remaining 2,100 serving overseas, 400 were appointed in London. Although men and women with scientific training are particularly welcome as candidates for general service entry (at present about 20 a year), there are not many scientists in Council service at present, but the Council hopes to increase the number of full-time science liaison and information posts. It also requires more men and women with scientific training as representatives and assistant representatives overseas. It also attaches importance to having men with a scientific training participating in the higher direction and planning of its work. The article, however, points out frankly that it is difficult for anyone serving the Council overseas to remain an active specialist in a scientific subject, unlike the librarian, for example, who will continue to use his expertise.

The 27 librarians serving the Council overseas play an important part in the Council's work, but until recently a Council career in librarianship meant a series of moves from country to country without advancement. Prospects have now improved and, apart from the upgrading of posts, some librarians have moved to posts of general responsibility. The article describes briefly the nature of the work overseas, and a brief section on the sciences indicates how here it is concerned with promoting science contacts: in the more advanced countries this entails liaison work at the research and postgraduate level, but in the less-developed countries the emphasis is on help and advice in teaching science. A realistic analysis of rewards and drawbacks in Council service overseas notes the recent improvements in pay, allowances and conditions of service and refers to the easements for officers and their wives serving in distant posts, especially in regard to family and educational problems which have been permitted as an indirect consequence of the Plowden Report on Overseas Services. Nevertheless, in terms of prestige and emoluments the normal ultimate ceiling is lower than in the Diplomatic Service and the main attractions are intangible.

Receipts from earnings and donations of £626,000 brought the Council's income for the year to £9,260,000, and for 1964-65 the Government grant of £8,634,000 in 1963-64 has been increased to £10,010,000, that from the Department of Technical Co-operation rising from

£233,000 to £371,000, largely for the cost of administering the increasing number of graduate volunteers. The Council also administers some £2 million provided by technical assistance schemes by the same Department, and the report refers particularly to the exceptionally close working relations between the Department and the Council, which now has representatives in more than 80 countries. It is still impossible to keep pace with the demand for various kinds of assistance in teaching English, and, of the 60 additional experts to serve in key English language teaching posts in the Commonwealth which it is planned to fill by 1970, 8 were appointed in the autumn of 1963, 12 in the autumn of 1964, and 10 are to be appointed in 1965. The Council continued to develop its work in English language teaching by television and has posted television officers for this purpose to India, Iran, Kuwait, Nigeria and the Sudan.

Of more than 64,000 overseas students now in Britain, a fifth are at universities, and although projects for 1,665 places in hostels in London and 1,471 elsewhere had been agreed in September 1964, besides the 1,226 additional places already available, the need for such accommodation remains urgent. Apart from such hostel accommodation, the £3 million voted by Parliament for the Overseas Students Welfare Expansion Programme administered by the Council goes to expanding the services provided at the Council's centres for overseas students and trainees in Britain. The Council is subsidizing an experiment at the Department of Education in the University of Sheffield on the development of programmed instruction in English for overseas students of scientific subjects. At the Department of Education in the University of Birmingham it is assisting research on tests of proficiency in English for overseas students. The National Foundation for Educational Research is being assisted in a large-scale survey of the problems which these students face in adjusting themselves to conditions of study in Britain, particularly the effect of the language factor.

Of some 476 specialist tours and advisory visits overseas arranged by the Council in 1963-64, 71 were concerned with science and technology, 85 with medicine, and 134 with education. It is estimated that almost 35 per cent of visitors and scholars coming to Britain in 1963-64, and of advisory visits and specialist tours overseas, were concerned with science and medicine: they included 118 scholars, bursars and others from the United Arab Republic, while 20 scientific and medical specialists from Britain visited that Republic. Of 8,851 overseas visitors to Britain assisted by the Council, 1,986 were concerned with science and technology, 1,110 with medicine, and 2,263 with education. Of 82 university interchange visits under the Commonwealth Scheme, 50 were for university teachers on study leave, 22 for postgraduate research workers and 10 for distinguished scholars invited for short visits. Under the Foreign Scheme there were 142 short visits, 4 longer teaching visits and 104 visits by young research workers.

## THE DESIGN OF SPECIFICATIONS FOR DRUGS

THIS account is based on a document produced by the Science Committee (Pharmaceutical Analysis) of the Department of Pharmaceutical Sciences of the Pharmaceutical Society of Great Britain. Recent advances in analytical techniques have revealed the presence in some drugs of hitherto unsuspected impurities with potent undesirable pharmacological effects. The Science Com-

mittee (Pharmaceutical Analysis) of the Department of Pharmaceutical Sciences has discussed the design of specifications as set out in the current British Pharmacopoeia and the British Pharmaceutical Codex, and it has formulated ideas for the future. The Committee's work has shown the need to apply a more critical approach to specifications for all drugs (see *Nature*, 203, 701; 1964).

The present conventional form of specification is in many instances unrealistic. This is particularly noticeable where in a group of drugs of a very similar chemical structure small differences in composition, or in the spatial arrangements of the molecule, may alter the potency considerably. Such slightly different compounds can be produced during synthesis so that impurities, generally of a lower potency but sometimes more toxic, remain in the commercially purified drug. These impurities are not necessarily detected by tests included in the specifications. The determination of the content of pure substances should be replaced by tests to limit the content of impurities. This change of emphasis is desirable even if an investigation of more fundamental physical properties were to enable a better assessment of the purity of a commercial sample of a drug to be made, or if methods could be devised to give more exact determinations of the percentage purity, particularly when pure reference substances are available for comparative assays. Moreover, tests for specific impurities can be applied to formulated products and thus give a better assessment of the quality of the drug used. Sensitive modern techniques make this practicable; formerly it was rarely possible.

**Stability tests.** In future, analytical assessment of the stability of the active ingredients of formulated products during storage must also be considered; limits for the content of decomposition products after a certain storage period should be included in monographs. For pharmaceutical purposes formulated products often contain other substances in much larger quantities than the active ingredients, and adequate standards for the purity of such substances must be specified, especially as many of these materials are not well-defined substances.

**Toxicity tests.** Toxicity tests should be made concurrently on the purest possible sample and on a sample of the same chemical at a certain stage of preparation. This stage should be where impurities, which the final purification should eliminate, are still present. Attention may also have to be given to products not refined by crystallization techniques, such as those purified by washing under controlled conditions or by the use of distillation or

sublimation methods. For any subsequent control purposes biological tests would seldom be required since, having established which of the impurities have to be controlled, these can be determined satisfactorily by chemical or physical methods.

**Non-toxic impurities.** A limit for non-toxic impurities such as non-active isomers or inactive hydrolysis products is also necessary, since they will diminish the potency of the material. The possible necessity of permitting a certain amount of impurity—even toxic impurity within clinically acceptable limits—in the interest of economy of manufacture should be recognized.

From the foregoing it follows that in future drug standards must include tests for all impurities that may be introduced during the manufacture of a drug. Clearly, each drug standard must include specific quantitative tests for possible impurities, with appropriate limits according to the toxicity of the impurity and the intended use of the drug. There should be a general test, such as phase-solubility measurement, thin-layer chromatography, gas-liquid chromatography, refractometry, etc., to limit total organic impurities. There should also be a screening test, for example, by emission spectrography, to detect any traces of toxic metal remaining in a purified drug as a result of the use of catalysts that a manufacturer might be reluctant to disclose, and limits should be laid down for any such contamination.

In order to formulate suitable specifications, the responsible committees must be provided with all relevant information. The disclosure of adequate details of the chemistry of a process and the practical details of each synthetic step, of the raw materials and solvents used, and some indication of probable impurities, will be essential. Although this would be best achieved by close co-operation between industry and the standardizing bodies, which has for the most part existed in the past, it may be necessary in fairness to all concerned to make such disclosure a legal requirement.

Once a drug has been standardized every new manufacturer would also have to comply with the full requirements of disclosure considered necessary when the drug was first approved.

## A CO-OPERATIVE APPROACH TO NON-DESTRUCTIVE TESTING

THE British National Committee for Non-Destructive Testing has given much consideration to the needs of industry in this field. Investigations by a working party under the chairmanship of Dr. E. G. Stanford have been described in a paper by Dr. A. Nemet<sup>1</sup>. Entrusted with the task of ascertaining the problems and difficulties in industry, the working party met representatives of three important engineering industries, the power generation industry, the aircraft industry, and the steel industry, and discussed these matters with them. The discussions revealed the keen interest of the different industries in non-destructive testing and in possible improvements of techniques. It was not difficult to find common ground within each industry and, in some cases, similarity of needs between industries which are in no way connected. There was clear indication of the wide scope for useful research and development work on methods of non-destructive testing and for co-operation between interested parties.

In November 1963, a second working party was appointed by the National Committee under the chairmanship of Dr. A. Nemet to examine further the needs of industry. The broad aims of the working party are: to confirm that a problem exists and is common in industry; to assess existing knowledge; to ascertain what bodies are doing relevant research; to ascertain what information is still required; to review means of utilizing this information as it is made available.

The working party is compiling a list of problems; it already includes a number of items such as investigation of fluorescent screens for high-energy radiations; attenuation effects of ultrasonic vibrations in solids; adhesive bonding appraisal, etc. It is hoped that university and college departments, Government laboratories, research associations and industrial organizations pursuing research or development work which may be helpful in this field may let the working party have an indication of their projects. It is also hoped that organizations using testing techniques may bring to the notice of the working party particular problems that they encounter or foresee.

Although the working party is limited, by its terms of reference, to finding and describing the most important problems, bringing together interested groups and making recommendations, it is already clear that there is much to be achieved by co-ordinated effort and by bringing the problems to the notice of Government and industrial organizations who could offer material help. Mention should be made of the valuable assistance and many courtesies extended to the working party by the Institution of Mechanical Engineers.

Correspondence should be addressed to the Secretary, The British National Committee for Non-Destructive Testing, The Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1.

<sup>1</sup> Nemet, A., *The Engineer*, February 23, 1963.

## APPLICATION OF THIN FILMS TO THE PRODUCTION OF USEFUL ELECTRIC CIRCUITS

THE eleventh meeting of the Dielectrics Evaporation Group was held at the Institute of Physics and the Physical Society during October 20-21. The following papers were read: "Ion Beam Deposition", by B. A. Probyn; "Thermally-grown, Pyrolytic and Sputtered Silicon Oxides", by M. J. F. Gaze and A. M. Gundlach; "The Use of Alloy Systems in the Epitaxial Growth of Silicon", by Dr. S. Nielson; "Progress in Reactive Sputtering of Oxide Films", by E. Hollands; "Effects of Film Composition on the Temperature Coefficient of Nickel-Chromium Resistive Films", by B. Hendry; "Factors Affecting Properties and Performance of Thin-film Microcircuits", by J. L. Parmee; "Techniques for Obtaining Films of Uniform Thickness", by B. Wood; "The Role of the Active Device in Thin-film Circuits", by D. Salisbury; "A Bakable Multiple-mask Changer", by Dr. P. R. Stuart; "Some Notes on the Recent American Vacuum Society Congress", by C. Stoddart.

The tone of this meeting inclined rather more to the technological aspects of thin films than the previous ones. However, it is sometimes salutary for the worker in pure research to pay heed to the more practical application of his work. The theme was in fact the application of thin films to the production of useful electronic circuits. One fact which emerged very clearly was the need for thin-film active devices the preparation of which should be compatible with the passive circuit elements commercially available. It is somewhat depressing to note that only a small amount of fundamental research has been carried out in Britain and elsewhere on compatible thin-film active devices. It was pointed out by Mr. Parmee that the only solution to this problem at present, and for some time to come, must be to attach a semiconductor device to a thin-film passive circuit. Such devices are now available in flakes which do not need separate leads. He also advocated, using compound methods of construction (evaporated conductors, reactively sputtered silica dielectrics and separately attached active devices), that reliable miniature assemblies can be constructed on a commercial

alternative approach to the device problem which has enjoyed widespread and influential support is the deposition of silicon on some suitable substrate. It was made clear by Dr. Nielson that this process has not yet been perfected. Many practical difficulties remain on the fundamental problem of producing monocrystalline films. It seems unlikely that this type can succeed at temperatures sufficient to avoid damage to more normal passive

components of the thin-film active device does not exist in the so-called 'solid circuit'. In this the problem

is the fabrication of integral passive circuit elements. Mr. Gaze compared silica films prepared by various methods in this connexion. He has been successful in forming capacitor films by thermal oxidation and pyrolytic deposition. This success may have influenced his decision not to persist in experiments on reactive sputtering for which Mr. Parmee had reported such excellent results.

The process of reactive sputtering is, due to its complexity, scarcely understood theoretically, and it is hoped that more fundamental research in this field may throw some light on the mechanism of deposition. In the practical field Mr. Hollands reported results on the sputtering of mixed titanates and of zirconia. He has confirmed that with mixed titanates, while high breakdown strengths may be obtained, they are associated with permittivities far lower than are to be expected from the bulk material. This phenomenon has been observed in other investigations of such materials. It is interesting to speculate whether or not in practice such a correlation will always be found. In the case of zirconia it was shown that adequate protection from moisture might cause a four-fold increase in dielectric strength.

Much interest is still shown in work on the preparation of nickel chromium alloy resistive films, and greater understanding of their properties is now emerging as a result of the combination of electrical measurements with electron microscope examination.

Evaporation is still the customary method of deposition. Mr. Wood described a method of producing uniform deposits over a large area using a line source and baffle plates. He used an optical transmission method for assessing uniformity of deposit as well as an optical analogue to determine the optimum geometry of the system.

Mr. Hendry related the changes in electrical properties for nickel chromium films of varying composition and different thicknesses to the structures shown by electron microscopy. He invoked the present theories of conduction in continuous and aggregated films appropriate to the different cases.

The approach of the vacuum engineer characterized the description of the bakable multiple-mask changer designed and made at the National Physical Laboratory for the preparation of cryotron arrays. This is suitable for operation in vacuum equipment at pressures down to  $10^{-6}$  mm mercury, and can hold up to 24 masks.

The meeting was concluded with an account of some of the more interesting papers at the recent American Vacuum Society Symposium. It is not clear when these will be published.

It is hoped that the next meeting of the Dielectrics Evaporation Group will be held some time before Easter 1965.

J. R. BALMER

## MAPS OF THE PERSEUS REGION AT 600 AND 1,415 MEGACYCLES PER SEC

By R. S. DIXON, S. Y. MENG and Prof. J. D. KRAUS

Radio Observatory, Ohio State University, Columbus, Ohio

MAPS of the Andromeda Nebula (*M* 31) region made at 600 and 1,415 Mc/s with the Ohio State University 260-ft. radio telescope have recently been published<sup>1</sup>. The maps covered 285 square degrees of sky between right

ascensions of 23h 40m to 02h 10m and declinations of 36° to 46° (N.). Since the telescope is of the meridian transit type and runs continuously, radiometric data were obtained during the same programme not only for the

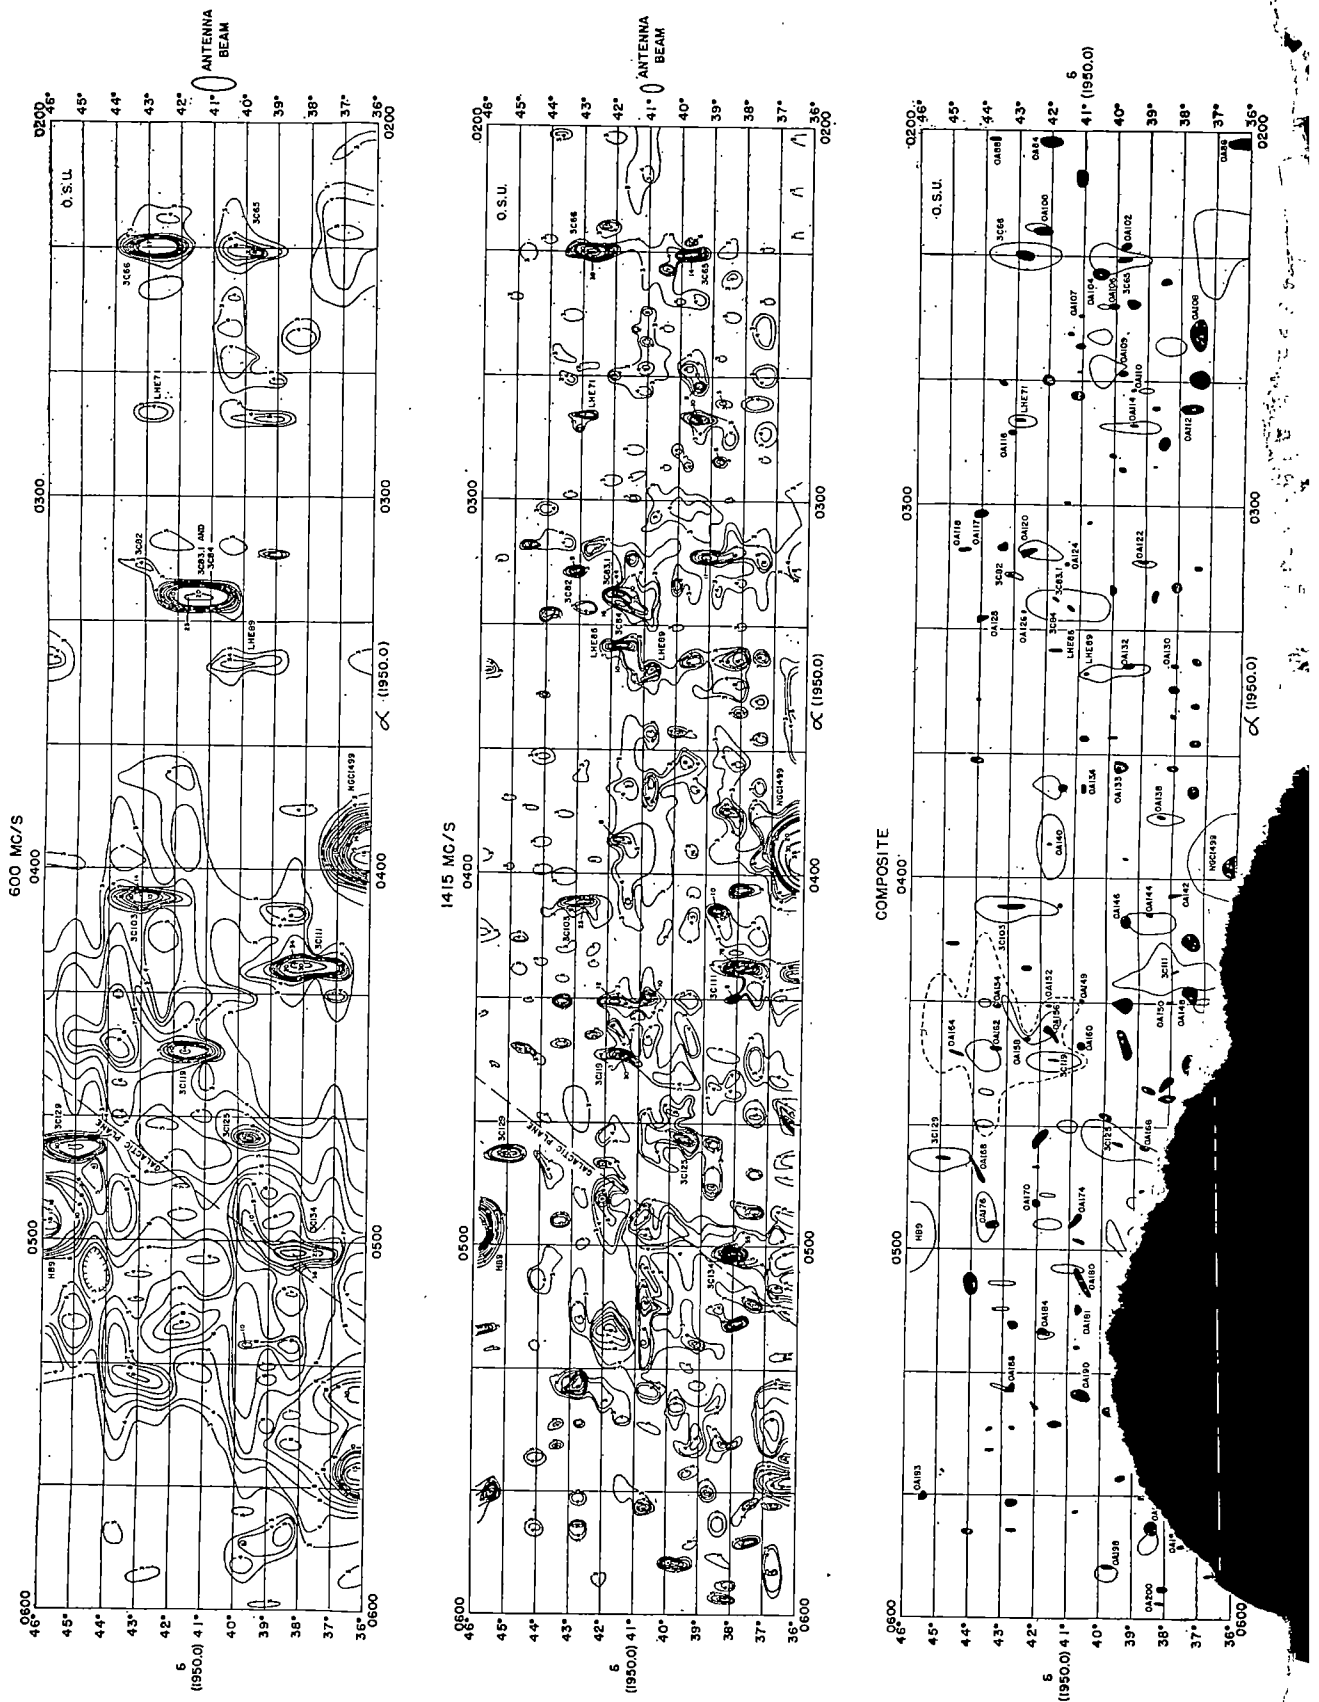

Fig. 1. Maps of the Perseus region made with the Ohio State University 280-ft. radio telescope at 600 Mc/s (top) and 1,415 Mc/s (middle). The bottom map is a composite one for comparing the positions of the most significant features of the other two maps by solid areas for 1,415 Mc/s and open contours for 600 Mc/s. The contour interval of the 600 Mc/s map is 0.25° K and of the 1,415 Mc/s map is 0.06° K antenna temperature

Andromeda region but for other areas in the zone between the declinations of 36° and 46°. The present article presents maps and results of observations with the Ohio State University telescope for a 450 square degree portion of that zone lying between right ascensions of 02h 00m and 06h 00m.

The 1,415-Mc/s receiver makes use of a liquid-nitrogen-cooled parametric amplifier with a noise temperature of 50° K. At 1,415 Mc/s the antenna beam-width is 11' × 36', the system temperature is 120° K, and with a 5-Mc/s bandwidth and a 12-sec integration time the root mean square noise temperature for one record is 0.025° K. The parameters of the 600-Mc/s system are 23' × 85', 650° K and 0.15° K, respectively. Two drift records were averaged for each declination, with the interval between adjacent declination scans being 20' at 1,415 Mc/s and 7' at 600 Mc/s. The region covered by this report contains approximately 4,000 beam areas at 1,415 Mc/s and 10 beam areas at 600 Mc/s.

The results of the observations are presented by the maps in Fig. 1. All are to the same scale. The top one gives antenna temperature at 600 Mc/s with contour spacings of 0.25° K. The middle map shows the antenna temperature contours at 1,415 Mc/s with intervals of 0.06° K. In both these maps the lowest two contours (1 and 2) are omitted, since they are closest to the root mean square noise temperature level and therefore probably the least significant. In addition, their absence greatly simplifies the appearance of the maps. Every tenth contour-level is indicated by a heavier line. Long-term residual drift was subtracted from the records so that the contour-levels are above an arbitrary zero level.

The bottom map is a composite map for comparing the positions of the most significant features of the upper two contour maps. In this composite map the 1,415-Mc/s sources are shown by solid areas and the 600-Mc/s sources by open contours. The size of the solid areas corresponds to the highest 1,415-Mc/s contour for a source, while the solid contours correspond to contour-level 4 (in a few cases) on the right half of the 600-Mc/s map and to somewhat higher levels on the left half in the vicinity of the galactic plane. Thus, the size of the solid and open areas show a correspondence. All positional information is epoch 1950.0.

An interesting region covered by these maps is that near the galactic plane. The position of the galactic equator has been given by Blaauw, Gum, Pawsey and Westerbasis. Indicated by a dashed line. The complex structure shown clearly in the 600-Mc/s map as it has reached the ninth contour level with a number of epitaxial features. An asymmetry of the ridge with respect to the galactic equator is also evident. In addition to a number of discrete sources near the galactic plane there arise even two clusters on the right-hand part of the continuous ridge and 03h 15m. These are most evident processes of the map. The dashed contour on the conveniently low temperatures a grouping near the galactic plane components. The sources listed in the revised third

The proper catalogue<sup>4</sup> in the area of our maps. All arise in the maps with the exception of 3 C 129.1. The sources 3 C 65, 66, 103, 111 and 119 as given by German and Long<sup>5</sup> were used as reference

Comparing our positions (at 1,415 Mc/s) with the values for the 3 C sources on our maps (3 C 83.1 and 84) yields a systematic difference of 1 sec of time in right ascension and 2 min of declination. These differences were regarded as small as to make any correction of our independently determined positions unwarranted. The standard deviation is 5 sec of time in right ascension and 1 min of arc in declination.

There are 9 additional sources on our maps in the list of Scott, Ryle and Hewish (SRH)<sup>6</sup>. Three of these are also listed by Long, Haseler and Elsmore (LHE)<sup>7</sup>. Comparing our positions with those in these lists (6 in one and 3 in the other) gives a systematic difference of 1 sec in time in

\* Probable error for OA sources: ± 10 s in R.A., ± 10' in dec.

† In units of 10<sup>-26</sup> W m<sup>-2</sup> (c/s)<sup>-1</sup>.

‡ In Scott, Ryle and Hewish list (ref. 6) (178 Mc/s).

§ LHE: Long, Haseler and Elsmore source (ref. 7) (408 Mc/s).

Note: Map sources OA 84, 86, and 88 are listed in ref. 1.

right ascension and 1 min of arc in declination, with standard deviations of 7 sec of time in right ascension and 4 min of arc in declination.

Those sources which appear at both frequencies in approximately the same position, or rise several contour intervals above the background at only one frequency, are considered to have a high probability of being real sources and are assigned OA (Ohio List A) numbers, provided they have not been previously named. These 59 new sources are shown with their OA numbers on the composite map. The positions and flux densities of all named sources found on the maps are listed in Table 1. The positions given are those measured at 1,415 Mc/s (epoch 1950.0), inasmuch as these are probably more accurate. Flux densities for the OA sources are probably correct to within ± 25 per cent. Adding the 59 OA sources of the present map to those previously published<sup>1</sup> brings the

published total to 110 O.A. sources in 715 square degrees of sky.

Three relatively strong sources appear at the extreme edges of the maps. These sources are NGC 1499 (California Nebula) at about 04h R.A. and 36° dec., HB 9 at about 05h R.A. and 46° dec., and an unnamed source at about 05h 45m R.A. and 36° dec. Since only small parts of these sources are within the map limits, they are not listed in Table 1.

During these observations, the telescope antenna and receivers were operated by G. Mikesell, S. R. O'Donnell, R. Townsend and W. Truss. We thank Drs. H. C. Ko and R. T. Nash for suggestions. This work was supported

in part by the U.S. National Science Foundation, the Air Force Cambridge Research Laboratories, and the Merzhon and Development Funds of the Ohio State University.

## GAMMA-RAY SPECTRA ANALYSED BY COMPUTER PROGRAMME USING THE PEAK AREA METHOD

By S. C. CHOY and R. A. SCHMITT

General Atomic Division of General Dynamics Corporation, John Jay Hopkins Laboratory for Pure and Applied Science, San Diego, California

AFTER considerable time had been devoted to manual analyses of more than 500 gamma-ray spectra, a computer programme was formulated, and it is now used routinely in the instrumental neutron activation analysis of meteorites<sup>1</sup>. In particular, our present research problem involves the determination, via instrumental neutron activation analysis, of the abundances (or concentrations) of selected chemical elements in meteorites and in separated meteoritic minerals and chondrules, etc. A known quantity of meteorite and appropriate reference standards are irradiated by thermal neutrons; afterwards, measurements are made of the gamma-rays of the radioactivities from the meteorites and reference standards of Na (15-h <sup>24</sup>Na), Mn (2.56-h <sup>56</sup>Mn), Cu (12.8-h <sup>64</sup>Cu), Cr (28-day <sup>51</sup>Cr), Fe (45-day <sup>59</sup>Fe), Sc (85-day <sup>46</sup>Sc), and Co (5.2-yr. <sup>60</sup>Co).

Typical gamma-spectra (see Figs. 1 and 2) result from the interaction of one or more gamma-rays in a scintillation detector, usually a 3-in. × 3-in. NaI(Tl) crystal coupled to a pulse-height analyser, usually 200 to 512 channels. The information from the analyser may be visually inspected via an X-Y plotter and also printed out on tape.

The abundances may be manually calculated by comparison of peak heights (corrected for radioactive decay) of selected prominent gamma-rays from known quantities of irradiated meteorites and reference standards.

The mathematical formulation of this computer programme follows the brief description given below; other methods of analysis have been given by Heath<sup>2</sup>. Peak areas of a selected gamma-ray (or rays) of both the irradiated reference standard and of the specimen are determined as follows. The ambient background spectrum is first subtracted, the subtraction being adjusted for differences in counting time for background, specimens, and reference standards. Background spectra are usually not subtracted from the reference standards, since counting rates of standards usually exceed the ambient background by many orders of magnitude. The Compton continuum, represented as a trapezoid under a given peak, is next calculated.

To calculate the concentration in p.p.m., the following items are included in the computer formulation: quantities of the specimen and reference standards expressed in g and  $\mu$ g units, respectively, and duration of counting and median counting times for specimen and standard, respectively. The printed result in p.p.m. also includes the standard deviation due to counting statistics.

Occasionally, the right-end plateau of a given peak in a specimen has such a steep drop-off that a straight line

initiating at the left minimum of a given peak may not be tangent-fitted to the Gaussian equation describing the right plateau. For calculation of such spectra, the  $\Delta$ -channel found for the corresponding reference standard peak is applied to the peak in the specimen. This  $\Delta$ -channel interval for the reference standard peak is the number of channels between the left-end minimum and the point where the tangent meets the right-end plateau Gaussian

Fig. 1.  $\gamma$ -Ray spectrum of Mokoia (0.257 g) after irradiation at  $2 \times 10^{11}$  neutrons/cm<sup>2</sup>-sec for 5 min and decay of 26 h (energy calibration at 12 keV/channel; 3 in. × 3 in. NaI(Tl) crystal)

Fig. 2.  $\gamma$ -Ray spectrum of Mokoia (0.257 g) after irradiation at  $2 \times 10^{12}$  neutrons/cm<sup>2</sup>-sec for 30 min and decay of 2 weeks (energy calibration at 12 keV/channel; 3 in. × 3 in. NaI(Tl) crystal)

equation. Multiplication of the number of  $\Delta$ -channels and the average of the channel data corresponding to these two extreme channel abscissa yields a fair approximation for the subtraction of the Compton continuum.

A check on the identity of radionuclides may be made by comparing the peak areas of two or more gamma-rays or by following the radioactive decay of a given peak area. The former has been provided for in the computer formulation. As an example, 2.56-h  $^{56}\text{Mn}$  is identified by requiring identical ratios of the peak areas of the 0.85-MeV and 1.81-MeV gamma-rays in the specimen and in the Mn reference standard. Peak areas of both gamma-rays are calculated as described above. Other identification examples are 15-h  $^{24}\text{Na}$  via ratios of the peak areas of the 1.37-MeV and 2.75-MeV gamma-rays, and 85-day  $^{45}\text{Sc}$  via ratios of the peak areas of the 0.89-MeV and 2.01-MeV sum gamma-rays.

When a composite peak contains two or more gamma-rays, interfering peak areas must be subtracted. Generally, this is done by selecting a peak for the interfering element which is itself free of interference in the spectrum of the specimen and determining its area,  $A$ . The area,  $B$ , of this peak in a reference standard of the interfering element is then determined, together with the area,  $C$ , in the same reference standard of the interfering line.  $AC/B$  is then subtracted from the composite line in the specimen spectrum. An illustration follows. In the composite twin peaks of  $^{56}\text{Fe}$ ,  $^{46}\text{Sc}$ , and  $^{60}\text{Co}$ , the peak areas of the 1.12-MeV gamma-ray of  $^{46}\text{Sc}$  and the 1.17-MeV and 1.33-MeV gamma-rays of  $^{60}\text{Co}$  must be subtracted to obtain the residual peak area of the 1.10-MeV and 1.29-MeV gamma-rays of  $^{56}\text{Fe}$ . The amount of  $^{46}\text{Sc}$  interference is simply found by multiplying the ratio of the 1.12-MeV peak area to the 2.01-MeV sum peak area of the  $^{46}\text{Sc}$  reference standard by the peak area of the 2.01-MeV sum peak area of  $^{46}\text{Sc}$  in the specimen. Similarly, the  $^{60}\text{Co}$  interference equals the product of the ratio of the 1.17-MeV and 1.33-MeV peak areas to the 2.50-MeV sum peak area and the 2.50-MeV sum peak area of  $^{60}\text{Co}$  in the specimen. Subtraction of these two quantities from the total composite peak area yields the residual  $^{56}\text{Fe}$  twin peak area. The standard deviation of the residual peak area includes all standard deviations of the interfering peak areas.

The abundances of the seven elements of interest are usually calculated in about 20 or more specimens in a single computer analysis against one set of reference standards. The programme also computes the mean concentration and the associated standard deviation of each element for a given set of specimens.

The peak-area method is relatively insensitive to gain shifts of the order of a few per cent. The programme also need be concerned only with peak-area information and not with the general Compton continuum with its satellite pair-peaks, backscatter peaks, etc. The peak areas of associated gamma-rays assume relevancy only under subtractive circumstances. Special cases arise when a gamma-ray of an unwanted radionuclide contributes to a particular peak area and no other gamma-ray(s) of that unwanted radionuclide exists. In most cases, differences in decay half-life will show up as two half-lives if the concentration values are plotted against spectral counting times.

**Numerical method.** The concentration of an element in a sample is found by comparing the area of a specified gamma-ray peak with that of a known standard that has been irradiated and counted under similar circumstances. The programme works with the raw counting data in the form of counts per channel for the sample, the standard, and the background. Other data needed by the programme are the counting time and the mean time-interval from a given time (such as the end of irradiation) for each spectrum, the mass of the irradiated standard and sample, the half-life of each standard element, and a first guess at the location of the channels which bound the peak to be studied. The background

Fig. 3. A typical example of a  $^{60}\text{Co}$   $\gamma$ -ray sum peak at 2.50 MeV with binomial equations fitted to the left minimum and right plateau. The solid curves are the approximating functions around the left end,  $X_1$ , and the right end,  $X_r$ . Circles are the real data points, and  $X_0$  is the first approximation point of the right end.

spectrum is subtracted from the sample and/or the standard spectrum at the user's option, and the Compton continuum is subtracted from both the sample spectrum and the standard spectrum before the areas are compared.

In order to compute the peak area, the programme first finds the low-energy bound of the peak,  $X_1$ , and the high-energy bound of the peak,  $X_r$  (see Fig. 3). The channel counts near  $X_1$  and  $X_r$  are approximated by a second-order polynomial and a Gaussian, respectively, as shown in Fig. 3 by the solid curves. The peak area is the area surrounded by the peak and the straight line drawn between the points  $(X_1, Y_1)$  and  $(X_r, Y_r)$ . The Compton continuum is the areas of the trapezoid under this straight line.

The low-energy bound of the peak is called the left end of the peak. It is assumed that the channel counts near the left end can be approximated by a second-order polynomial of the form:

$$Y = a_1 X^2 + b_1 X + c_1 \quad (1)$$

where  $a_1$ ,  $b_1$  and  $c_1$  are the constants which give the least-squares deviation of  $Y$ 's from the actual counts.  $X$  is a channel number and  $Y$  is a channel count.

The user of the programme has to specify the channels within which the real left-end point lies. The programme first finds the channel number which has the smallest count among the specified channels. Then, using this channel as a midpoint and using the two channel numbers on each side of it, the programme finds the coefficients in equation (1). The minimum point of equation (1),  $X_1$ , is considered to be the left end of the peak:

$$X_1 = -\frac{b_1}{2a_1} \quad (2)$$

where  $a_1$  must be positive.

To check that the point  $X_1$  is an acceptable left end of the peak, the programme looks to see if  $X_1$  lies within the channel numbers that have been used to compute the coefficients in equation (1) and if the coefficient  $a_1$  is positive. If not, the programme uses one more channel on each side of the midpoint to find a new set of coefficients and a new  $X_1$ . The programme repeats this procedure

until an acceptable  $X_l$  is found, or stops further computation if an acceptable  $X_l$  is not found after all the specified channels are used.  $Y_l$ , the channel count corresponding to the channel  $X_l$ , is found by substituting  $X_l$  into equation (1).

The high-energy bound of the peak is called the right end of the peak. The channel counts near the right end are approximated by a Gaussian function of the form:

$$\ln Y = a_2 X^2 + b_2 X + c_2 \quad (3)$$

where  $a_2$ ,  $b_2$  and  $c_2$  are the constants which give the least-squares deviation of  $\ln Y$ 's from the logarithms of the actual counts.  $X$  is a channel number and  $Y$  is a channel count. In the polynomial fit, the user of the programme has to specify the channels that are to be used to compute the coefficients in equation (3). If the number of the specified channels is less than or equal to nine, the programme uses all the specified channels to compute the coefficients in equation (3). If the number (which is restricted to be an odd number) is greater than nine, it uses the central nine channels of those specified to compute the coefficients. Then the programme checks the sign of the coefficient  $a_2$ . If  $a_2$  is positive, the programme proceeds with the tangent method; if  $a_2$  is zero or negative, the programme has the following choice: First, if all the specified channels have already been used to compute the coefficients in equation (3), the programme proceeds with the  $\Delta$ -channel method as an alternative. Secondly, if not all the specified channels have been used to compute the coefficients, the programme uses two more channels to obtain a new set of the coefficients,  $a_2$ ,  $b_2$  and  $c_2$ .

In the tangent method, the right end of the peak,  $X_r$ , is defined to be the point where the straight line drawn from the left-end point ( $X_l$ ,  $Y_l$ ) is tangent to equation (3). For the first approximation to  $X_l$ , a minimum point of equation (3),  $X_0 = -(b_2/2a_2)$ , is used if  $X_0$  lies within the points that have been used to find the coefficients in equation (3). If the minimum point does not lie within these points, the extreme right-end point, again called  $X_0$ , is used as the first approximation. Using this  $X_0$  value, the real right end (the tangent point  $X_r$ ) is found as follows:

By differentiating equation (3), we get

$$Y' = (2a_2 X + b_2) \exp(a_2 X^2 + b_2 X + c_2)$$

At  $X = X_r$ ,

$$Y'_{X=X_r} = (2a_2 X_r + b_2) \exp(a_2 X_r^2 + b_2 X_r + c_2) \quad (4)$$

But  $Y'_{X=X_r}$  must be equal to the slope of the tangent line—starting at the point ( $X_l$ ,  $Y_l$ ) and drawn to the point ( $X_r$ ,  $Y_r$ )—which has the tangent of  $(Y_r - Y_l)/(X_r - X_l)$ . Therefore:

$$\frac{Y_r - Y_l}{X_r - X_l} = (2a_2 X_r + b_2) \exp(a_2 X_r^2 + b_2 X_r + c_2)$$

Substitution of  $Y_r = \exp(a_2 X_r^2 + b_2 X_r + c_2)$  into the above equation gives:

$$[(X_r - X_l)(2a_2 X_r + b_2) - 1] \exp(a_2 X_r^2 + b_2 X_r + c_2) + Y_l = 0 \quad (5)$$

Equation (5) is solved iteratively by the Newton-Raphson method to find  $X_r$ . That is:

$$X_{r,n+1} = X_{r,n} - \frac{f(X_{r,n})}{f'(X_{r,n})}$$

where  $X_{r,n}$  is the  $n$ th approximation of  $X_r$  (note that  $X_{r,1} = X_0$ , our first approximation),

$$f(X) = [(X - X_l)(2a_2 X + b_2) - 1] \exp(a_2 X^2 + b_2 X + c_2) + Y_l \quad (6)$$

and

$$f'(X) = (X - X_l)[(2a_2 X + b_2)^2 + 2a_2] \exp(a_2 X^2 + b_2 X + c_2) \quad (7)$$

To check that the point  $X_r$  is an acceptable right end of the peak, the programme looks to see if  $X_r$  lies within the points that have been used to compute the coefficients in equation (3). If not, the programme has the following choice: First, if all the specified channels have already been used to compute the coefficients in equation (3), the programme uses the  $\Delta$ -channel method as an alternative. Secondly, if not all the specified channels have been used to find the coefficients previously, the programme uses two more points to get a new set of coefficients  $a_2$ ,  $b_2$ , and  $c_2$ , and repeats the procedure in entirety.

If the tangent method fails to find an acceptable right end of the peak, the  $\Delta$ -channel method is used as an alternative. The  $\Delta$ -channel is defined to be the number of channels which is added to the left-end point,  $X_l$ , to find the right end,  $X_r$ . The user of the programme has to specify the  $\Delta$ -channel for the standard if the  $\Delta$ -channel method is to be used to find the right end of the peak of the standard in case the tangent method fails. But the programme automatically uses the  $\Delta$ -channel method for the sample if the tangent method fails to find an acceptable right end. The  $\Delta$ -channel of the sample is assumed to be equal to  $X_r - X_l$  of the corresponding peak of the standard spectrum.

*Area of the peak and its standard deviation.* The total area under the peak,  $C$ , with the low-energy bound  $X_l$  and the high-energy bound  $X_r$  is computed by the trapezoidal rule, and its standard deviation,  $\sigma_C$ , is given by  $\sqrt{C}$ . The Compton continuum,  $B$ , is defined to be the trapezoid under ( $X_l$ ,  $Y_l$ ) and ( $X_r$ ,  $Y_r$ ), and its standard deviation,  $\sigma_B$ , is given by  $\sqrt{B}$ . Note that  $Y_l$  is found by substituting  $X_l$  into equation (1), and that  $Y_r$  is found by substituting  $X_r$  into equation (3). The peak area of interest here,  $A$ , is found by subtracting  $B$  from  $C$ , and its standard deviation:

$$\sigma_A = \sqrt{\sigma_C^2 + \sigma_B^2}$$

## COVALENT RADII OF CERTAIN METAL IONS AND THE LENGTH OF THE METAL-METAL BONDS

By M. J. BENNETT and PROF. R. MASON

Department of Chemistry, University of Sheffield

**C**OVALENT radii of metal ions in unusual oxidation states. The availability of a number of accurate X-ray analyses of bond lengths in organometallic molecules appears to provide values for radii of metal ions of formal

oxidation state rarely met in transition metal complexes *per se*. The data required for the present analysis are summarized in Table 1; it is to be noted that in  $\pi$ -cyclopentadienyl derivatives, assignment of the formal oxida-

Table 1. BOND LENGTHS IN SEVERAL ORGANOMETALLIC MOLECULES

Manganese	$\{\pi\text{-C}_5\text{H}_5\}_2\text{Mn}(\text{CO})_3$ $\{\pi\text{-C}_5\text{H}_5\}_4\text{Mn}(\text{CO})_3$ diars	4	$\text{MnI} \rightarrow \text{C}(\text{C}_2\text{H}_5)$	2.155 (avg.)
		5	$\text{MnI} \rightarrow \text{C}(\text{C}_2\text{H}_5)$	2.15 (avg.)
Cobalt	$\pi\text{-C}_5\text{H}_5\text{C}_5\text{H}_5\text{C}_5\text{H}_5\text{Co}$ $\pi\text{-C}_5\text{H}_5\text{C}_5\text{H}_5\text{C}_5\text{H}_5\text{Co}$	6	$\text{CoIII} \rightarrow \text{C}(\text{C}_2\text{H}_5)$	2.07 (avg.)
		7	$\text{CoIII} \rightarrow \text{C}(\text{C}_2\text{H}_5)$	2.07 (avg.)

tion state of the metal ion relies on the  $\pi\text{-C}_5\text{H}_5$  anion being regarded as a six-electron donor. This procedure is entirely arbitrary but is acceptable provided self-consistency is maintained.

This limited survey immediately suggests that the 'covalent' radius of a cyclopentadienyl carbon is essentially identical ( $\pm 0.03$  Å) with that of a simple tetrahedral  $\sigma$ -bonded carbon atom. This is evidenced by the equality of molybdenum-carbon bond lengths in  $\pi\text{-C}_5\text{H}_5\text{MoC}_2\text{H}_5(\text{CO})_3$  (ref. 1) apart, that is, from the  $\text{Mo} \rightarrow \text{C}(\text{O})$  bond lengths, and by the bond lengths in the  $\text{CoIII}$  examples. The octahedral covalent radius of  $\text{Co}^{2+}$  can be estimated as  $1.30 (\pm 0.03)$  Å from the bond lengths in  $\text{CO}(\text{NH}_3)_3(\text{NO}_2)_2\text{Cl}$  (ref. 8), using a chlorine radius of  $1.00$  Å and a value of  $0.70$  Å for nitrogen, and as  $1.27$  Å from azidopentamine cobalt(III) azide<sup>9</sup>. The bond lengths of  $2.07$  Å in the  $\pi\text{-cyclopentadienyl}$  derivatives therefore suggest a 'covalent' radius for a cyclopentadienyl carbon as  $0.77\text{--}0.80$  Å. Clearly the simplicity of this 'hard-ball' approach implies a certain lack of generalization, but for certain metal configurations, in particular  $d^6$  with the exception of  $\text{Fe(II)}$ , the agreement is satisfyingly good. As such, we can calculate effective metal radii and these are listed in Table 2. Kilbourn and Powell<sup>11</sup> give a value of  $1.31$  Å for the manganese radius in *bis*(pentacarbonylmanganese) diphenyltin. Depending on one's view of the bonding in this complex, the oxidation state of the transition metal ion is  $+1$ ,  $0$  or  $-1$ . In all these cases, however, some shortening of the Mn-Sn bond distance may take place through  $d\pi\text{--}d\pi$  bonding, so that it is not surprising that the Kilbourn and Powell value is smaller than we suggest.

Table 2. RADII OF MOLYBDENUM AND MANGANESE IONS

Metal ion	Radius	Comments
$\text{MoIV}$	$1.52 \pm 0.03$ Å	Formally eight co-ordinate
$\text{MoI}$	$1.60 \pm 0.03$ Å	Formally seven co-ordinate
$\text{MnI}$	$1.38 \pm 0.03$ Å	Formally octahedral, identical with value derived from $[(\text{CO})_5\text{MnBr}]_2$ (ref. 10) using bromine radius of $1.14$ Å

**The length of metal-metal bonds.** The observed manganese-manganese bond length of  $2.93$  Å in  $\text{Mn}_2(\text{CO})_{10}$  (ref. 12) is not substantially greater than would be expected. A calculated bond length of  $2.76$  Å is obtained for  $\text{Mn(I)} \rightarrow \text{Mn(O)}$  and we should clearly anticipate a greater value for  $\text{Mn(O)} \rightarrow \text{Mn(O)}$ . Judged by bond length differences in other organometallic molecules, the change in metal radius following unit change of oxidation state is of the order of  $0.05$  Å, so that the sum of radii for  $\text{Mn(O)}$  is  $2.86$  Å. This value is only  $0.07$  Å less than the observed result and, while this difference must not be taken too literally in view of the unsophisticated methods by which it was obtained, it does seem clear that Cotton and Monchamp<sup>13</sup> were correct in finding it "difficult to believe" that a metal-metal bond stretched by about  $0.5$  Å could be as strong as  $34$  kcal/mole. The earlier suggestion<sup>3</sup>, that the Mo-Mo bond in the supersandwich  $\{\pi\text{-C}_5\text{H}_5\text{Mo}(\text{CO})_3\}_2$  is long, as a result of steric strain, has been questioned some time ago<sup>1</sup> on the basis of the similarity of its structure to that of  $\pi\text{-C}_5\text{H}_5\text{MoC}_2\text{H}_5(\text{CO})_3$  where such possible steric interactions must be absent.

**The nature of the metal orbitals in  $\text{Mn}_2(\text{CO})_{10}$ .** While, as was mentioned earlier, the precise value by which the

Fig. 1. Diagrammatic representation of the carbonyl arrangement in  $\text{Mn}_2(\text{CO})_{10}$ 

observed bond length in  $\text{Mn}_2(\text{CO})_{10}$  is greater than the sum of metal radii is open to doubt, it does seem clear that, taken with the structure of  $\{\pi\text{-C}_5\text{H}_5\text{Mo}(\text{CO})_3\}_2$ , we wish to explain a difference of the order of  $0.1$  Å. In  $\text{Mn}_2(\text{CO})_{10}$ , the two  $\text{Mn}(\text{CO})_5$  moieties are in a staggered conformation so as, one may presume, to minimize intramolecular repulsions between the non-bonded carbonyl groups. It is therefore surprising to find that the distances between these groups are decreased from what they would be in a perfectly symmetrical situation by the separate carbonyl groups bending towards one another (Fig. 1). Moreover, it is unlikely that such distortions can be explained as originating from, say, crystal packing effects, because an identical situation has been described as existing in  $\text{Mn}(\text{CO})_5\text{H}$  (ref. 14). We can investigate the effect of these small angular distortions on the Mn-Mn  $\sigma$  bond by considering the  $\text{Mn}(\text{CO})_5$  radical; the character of the orbital directed along the 'z' axis, housing the unpaired electron, is examined for two situations: (i) the manganese lies exactly in the plane defined by the four carbonyl groups, and (ii) the manganese and four carbons are non-coplanar in the sense that the angles between the orbital  $\chi_z$ , directed along the 'z' axis, the manganese and the four carbons are  $85^\circ$ —a value which represents the trend of the experimental results in  $\text{Mn}_2(\text{CO})_{10}$  and  $\text{Mn}(\text{CO})_5\text{H}$ .

The numbering of atoms is shown in Fig. 2.

Fig. 2

To obtain some idea of the qualitative changes involved in going from the symmetrical to the unsymmetrical structure, we assume all carbonyl groups are equivalent. For the symmetrical structure the overlap matrix for the angular part of the wave functions only is as shown in Table 3.

Table 3

Metal orbitals	Ligand orbitals				
	$\varphi_1$	$\varphi_2$	$\varphi_3$	$\varphi_4$	$\varphi_5$
$s$	1	1	1	1	1

$p_x$	$\sqrt{3}$	0	$-\sqrt{3}$	0	0
$d_{xz}$	0	0	0	0	0
$d_{yz}$	0	0	0	0	0
$p_y$	0	$\sqrt{3}$	0	$-\sqrt{3}$	0
$d_{x^2-y^2}$	$\sqrt{15}/2$	$-\sqrt{15}/2$	$\sqrt{15}/2$	$-\sqrt{15}/2$	0
$d_{zz}$	0	0	0	0	0

Table 4

Metal orbital	Ligand orbital				
	$\varphi_1$	$\varphi_2$	$\varphi_3$	$\varphi_4$	$\varphi_5$
$s$	1	1	1	1	1
$p_z$	$\sqrt{3} \cos 85^\circ$	$\sqrt{3} \cos 85^\circ$	$\sqrt{3} \cos 85^\circ$	$\sqrt{3} \cos 85^\circ$	$-\sqrt{3}$
$d_{z^2}$	$\sqrt{5}/2(3 \cos^2 85^\circ - 1)$	$\sqrt{5}/2(3 \cos^2 85^\circ - 1)$	$\sqrt{5}/2(3 \cos^2 85^\circ - 1)$	$\sqrt{5}/2(3 \cos^2 85^\circ - 1)$	$\sqrt{5}$
$f_x$	$\sqrt{3} \sin 85^\circ$	0	$-\sqrt{3} \sin 85^\circ$	0	0
$d_{xz}$	$\sqrt{15} \sin 85^\circ \cos 85^\circ$	0	$-\sqrt{15} \sin 85^\circ \cos 85^\circ$	0	0
$p_y$	0	$\sqrt{3} \sin 85^\circ$	0	$-\sqrt{3} \sin 85^\circ$	0
$d_{yz}$	0	$\sqrt{15} \sin 85^\circ \cos 85^\circ$	0	$-\sqrt{15} \sin 85^\circ \cos 85^\circ$	0
$d_{x^2-y^2}$	$\sqrt{15}/2 \sin^2 85^\circ$	$-\sqrt{15}/2 \sin^2 85^\circ$	$\sqrt{15}/2 \sin^2 85^\circ$	$-\sqrt{15}/2 \sin^2 85^\circ$	0
$d_{xy}$	0	0	0	0	0

The orbitals  $d_{xy}$ ,  $d_{xz}$  and  $d_{yz}$  are now orthogonal to the five ligand  $\sigma$  orbitals  $\varphi_1 \dots \varphi_5$ , and a further orthogonal orbital, in which the unpaired electron must be placed, can be readily constructed from a linear combination of the metals ' $s$ ', ' $p_z$ ' and ' $d_{z^2}$ ' orbitals. Orthogonality is satisfied by the wave function:

$$\chi = \sqrt{5}/2 s + d_{z^2} + \sqrt{15}/2 p_z$$

which on normalization gives:

$$\chi_z^1 = 0.456s + 0.408d_{z^2} + 0.791p_z \quad (1)$$

The equivalent orbital matrix can be set up for the unsymmetrical structure (Table 4).

As before,  $d_{xy}$  is orthogonal to the ligand orbitals but  $d_{xz}$  and  $d_{yz}$  must be mixed with  $p_y$  and  $p_z$  to become orthogonal and hence the other non-bonding orbitals. The required linear combinations are:

$$\psi_2 = \frac{d_{xz} - \sqrt{5} \cos 85^\circ p_x}{(1 + 5 \cos^2 85^\circ)^{1/2}}$$

and:

$$\psi_3 = \frac{d_{yz} - \sqrt{5} \cos 85^\circ p_y}{(1 + 5 \cos^2 85^\circ)^{1/2}}$$

giving the three orthonormal non-bonding orbitals as:

$$\chi_1 = d_{xy}$$

$$\chi_2 = 0.982d_{xz} - 0.191p_x$$

and:

$$\chi_3 = 0.982d_{yz} - 0.191p_y$$

The fourth orthogonal orbital is built up as before from the  $s$ ,  $p_x$  and  $d_{z^2}$  orbitals:

$s$	1	1	1	1	1
$p_x$	0.151	0.151	0.151	0.151	-1.732
$d_{z^2}$	-1.093	-1.093	-1.093	-1.093	2.236

and the required normalized orbital is:

$$\chi_z^{11} = 0.378s + 0.803p_x + 0.460d_{z^2} \quad (2)$$

We can see therefore that the angular distortions of the carbonyl groups from strict square pyramidal symmetry about the manganese ion lead to an increase in the ' $p$ ' and ' $d$ ' character in the orbital directed along the axis of the metal-metal ' $\sigma$ ' bond in  $Mn_2(CO)_{10}$ . While in this molecule the sense of the distortion would be thought to have the consequence of increasing repulsions between the non-bonded carbonyl groups, repulsion terms will be effectively reduced by: (i) the Mn-Mn bond length being greater as a result of the new hybrid orbital having greater ' $p$ ' and ' $d$ ' character, and (ii) the mixing of ' $p$ ' character

Fig. 3

into the non-bonding orbitals  $d_{xz}$  and  $d_{yz}$  decreases repulsions between these orbitals (Fig. 3).

A far less satisfactory calculation can be made for the 'supersandwich'  $\{\pi-C_5H_5Mo(CO)_3\}_2$  since the assumption of equality of ligand groups around the metal ion cannot be made in any reasonable sense. An application of the maximum overlap criterion to the structure of  $\pi-C_5H_5C_2H_5-Mo(CO)_3$  (ref. 1) does, however, indicate that the metal orbitals used for bonding to the doubly degenerate  $e$  orbitals of the cyclopentadienyl anion, which formally are the degenerate  $d_{xz}$  and  $d_{yz}$  orbitals (or hybrids), are not degenerate. They contain differing amounts of ' $d$ ' and ' $p$ ' character, a feature which explains the observed lack of five-fold symmetry in the bonded cyclopentadienyl ligand<sup>15</sup>.

Two points need emphasis. The derivation of metal radii from the  $\pi$ -cyclopentadienyl complexes is a simplification which must not be relied on to provide accurate values; rather, it is the trend among a related class of compounds which is instructive. A shortcoming of our overlap analysis is clearly connected with the use of the angular part of the metal wave functions only; this is not serious here, we feel, since the method attempts to derive differences between structures which are very similar. The method cannot be used to obtain precise orbital coefficients until such factors as the  $\pi$ -bonding of the ligands, effective nuclear charge of the metal and so on are taken into account.

# TENSILE STRENGTH OF INDIVIDUAL COMPRESSION WOOD FIBRES AND ITS INFLUENCE ON PROPERTIES OF PAPER

By DR. J. M. DINWOODIE

Forest Products Research Laboratory, Princes Risborough, Bucks

A LIMITED amount of evidence is available to indicate that compression wood fibres produce pulps which are significantly low in most strength properties compared with pulp produced from normal wood<sup>1,2</sup>. The influence is particularly striking in the case of the tearing resistance of papers. Tearing resistance has been related in the past to fibre length and to fibre stiffness<sup>3-5</sup>, while the breaking length, burst factor and fold endurance are determined primarily by the bonding capacity of the fibres and, as such, by the flexibility of the fibres as determined by their diameter, cell wall thickness and density.

Within the last few years the hypothesis has been presented that the tensile strength of the individual fibres is important in determining most of the strength properties of the paper<sup>6-9</sup> with a possibly greater significance with regard to tear than to breaking length, burst and fold<sup>6,8</sup>. It was considered that this hypothesis could be readily tested on the known large differences in some of the strength properties between normal wood pulp and compression wood pulp. This procedure is preferred to the selection of different species, for, although this would provide a wide range in tear and breaking length, it would introduce larger variations in fibre length, diameter, wall thickness and density than is obtained in the comparison of normal and compression wood of a single species. In addition, new information on the relative strength of normal and compression wood fibres would be obtained.

The compression wood in four logs, each from a different species, was separated from the normal wood and pulped separately, using a kraft liquor. Each log contained approximately 30 growth rings and, since the compression wood was generally restricted to the outer rings, the first 15 rings from the pith of the normal wood was discarded, thus rendering the pulp samples more comparable in anatomical and chemical properties. Since the lignin content influences both the fibre strength<sup>9</sup> and the physical properties of the paper<sup>10</sup>, all the pulps were cooked to a

Kappa number of 25. This entailed cooking the compression wood either for a longer period or with an increase in the percentage of active alkali from 20 to 25.

The pulp properties of the normal and compression wood are presented in Table 1. The tear factor (T.f.) of the compression wood pulp is substantially lower (30 per cent) than the normal wood pulp. The breaking length (B.L.) and burst factor (B.f.) of normal and compression wood pulps are comparable, but compression wood pulp does not develop so well on beating and there is an appreciable difference in the strength properties of the beaten pulps. The air-resistance factor (A.R.f.) of both unbeaten and beaten pulps from the compression wood is higher by about 50 per cent; this is not reflected in the freeness.

Fifty fibres from each of the nine samples were mounted on paper tags with ethylhydroxyethyl cellulose by a method slightly modified from that of Hartler, Kull and Stockman<sup>11</sup>. The fibres were strained in a controlled environment on an Instron tensometer with a rate of loading of 0.005 in./min. Approximately 50 per cent of the fibres failed near the point of gluing, but a 't' test indicated no significant difference in the strengths of fibres failing in the free zone and near the glue. The cross-sectional area of the cell wall was determined on 50 fibres removed from each of the same fibre suspensions as were the fibres that were strength-tested. This technique is considered to be adequate, since the prime consideration is the relative cell wall area of the various fibre samples.

The tensile strengths are recorded in Table 1, and the values for normal wood fibres agree well with the limited amount of published data<sup>7,12</sup>. The strength of the compression wood fibres is appreciably lower (46 per cent) than that of the normal wood and, of the fibre properties measured, only the degree of polymerization of the cellulose, as indicated by viscosity measurements (Tappi Standard T206 with 0.5 per cent solution), varies in a

N, normal wood; C, compression wood; l, fibre length; d, fibre diameter; w, wall thickness of fibre. C.S.F., Canadian Standard Freeness.

\* Two samples of *P. abies* were averaged before calculating the mean of four samples.

† Difference/mean per cent.

Fig. 1. The relationship between the tensile strength of individual fibres of normal (●) and compression (×) wood and the viscosity of their cellulose. \*\*\*, Significant at the 0.1 per cent level

Fig. 2. The dependence of the tear factor of unbeaten pulp on the tensile strengths of the individual fibres. ●, Normal wood; ×, compression wood. \*\*, Significant at the 1 per cent level

manner which may explain the difference. The relationship between the fibre tensile strength and the viscosity of the cellulose is presented in Fig. 1, while Fig. 2 shows the relationship between the tearing resistance of the paper and the tensile strengths of the individual fibres.

Bonding can only increase the breaking length and burst where there is adequate fibre strength, and it would appear that this latter property is the limiting factor in the development of the beaten strength of the compression wood pulp (Table 1). Since the breaking length and burst of the unbeaten compression wood pulp are similar to those of the normal wood, it would appear that, at least in long-fibred low-density pulps, tearing resistance is more sensitive to variation in fibre strength than are breaking length and burst.

The considerably higher air-resistance of the compression wood paper is probably associated with factors modified during sheet formation, such as the degree of fibre collapse, since the freeness of the pulp suspensions is unaffected, and it is extremely unlikely that fibre strength *per se* influences the resistance of the fibre web to the passage of air.

It could, however, be argued, from the experimental evidence which has been described, that the decrease in viscosity, which resulted in a decrease in the tear factor of the compression wood, is the result of the more severe cooking conditions of the compression wood samples.

Evidence is available to indicate that degradation of the cellulose does occur in kraft cooking at 160°–170° C<sup>14,15</sup>, but it would appear that most of this occurs in the initial stages, after which the degree of polymerization decreases only slowly<sup>14–16</sup>. From the work of Ahlm and Leopold<sup>16</sup> on the cooking of loblolly pine (*Pinus taeda*), the decrease in degree of polymerization with increasing cooking time from 105 min to 210 min (see Table 1) was only 14 per cent, while McIntosh<sup>17</sup> records no difference during this increase in cooking time. Dadswell, Wardrop and Watson<sup>2</sup> found no difference in the strength properties of compression wood samples cooked for the same time but with active alkali concentrations of 20 and 25 per cent, and Stone and Clayton<sup>18</sup> record only a slight decrease in fibre strength with decrease in lignin content. Thus, while the possibility that the decrease in viscosity of the compression wood fibres is induced by the slight differences in cooking conditions cannot be eliminated, the evidence is such as to indicate the probability that the greater part of the viscosity difference is inherent. The nature of the investigation did not permit cooking time, liquor concentration and lignin content to be held constant simultaneously.

Substantiating evidence of the importance of fibre strength in determining the tearing resistance of paper is available from recorded work<sup>7,13</sup> and is supported by some of our own unpublished work. In sulphate pulps there is an increase in the number of fibres broken in the tear tests compared with breaking-length tests, inferring a closer and more critical relationship between fibre strength and tear than between fibre strength and breaking length.

It may be concluded from this limited investigation that there is a high probability that the tensile strength of individual compression wood fibres is considerably lower than that of normal fibres. This appears to be related to a decrease in the degree of polymerization of the compression wood fibres. Another possible explanation for the lower strength values of the compression wood fibres is the frequent spiral fissuring of the cell wall.

The results obtained support the view that individual fibre strength is of prime importance in determining the tearing resistance of paper. It is also significant in determining the breaking length and burst factor, but only in paper from beaten pulp.

## DIFFUSION OF PHOSPHATE TO PLANT ROOTS

By DR. D. G. LEWIS and PROF. J. P. QUIRK\*

Department of Biochemistry and Soil Science, Waite Agricultural Research Institute, Private Bag No. 1, Glen Osmond, South Australia

SCHOFIELD<sup>1</sup> has pointed out the necessity of considering both capacity and intensity factors when assessing the availability of plant nutrients. Plant growth, however, is a dynamic process in which ion transport phenomena are involved, both within the soil and within the plant. Nutrient transport in the soil can occur as mass flow of the soil solution and also by diffusion. Opinion has been divided as to the relative importance of each of these mechanisms, particularly in regard to phosphate<sup>2-5</sup>. Strong evidence that diffusive flow can supply all the phosphate required by a growing plant has now been obtained.

The accumulation of phosphate by wheat plants has been followed as a function of time over a complete growth cycle, and the rate of uptake compared with a computed uptake if diffusion alone contributed. The soil used for both pot experiments and laboratory investigations was the Seddon sandy loam for which some data on phosphate retention have been obtained by Kanwar<sup>6</sup>. Phosphate additions of 150, 300 and 600  $\mu\text{g P/g}$  soil were made to bulk samples of soil by spraying on appropriate amounts of calcium phosphate solution, followed by drying and thorough mixing. Wheat plants were grown under conditions of controlled environment in small pots of these soils and the plant tops were collected and analysed at intervals of two weeks from sowing to maturity (22 weeks). The rate of phosphate uptake was almost constant during the period 2–12 weeks and the mean rates for the three phosphate-levels were 2.7, 5.6 and 12.0  $\mu\text{g P/plant/h}$ .

For the calculation of phosphate supplied to the root by diffusion, a physical model was adopted in which the root was considered to be a cylindrical sink towards which phosphate ions would diffuse under the influence of a concentration gradient induced by active uptake at the root surfaces; that is, flow would be radial at all times from an infinite unstirred medium of uniform initial phosphate concentration  $P_0$ . Since the concentration of phosphate near the root surface could not be measured, some estimate was necessary to enable mathematical calculations to be made. In this work the boundary condition imposed was that the phosphate concentration at the root surface decreased exponentially with time from the initial value  $P_0$ .

For this system a general diffusion equation can be written as follows, using cylindrical polar co-ordinates:

$$\frac{\partial C}{\partial t} = \frac{1}{r} \frac{\partial}{\partial r} \left( r D \frac{\partial C}{\partial r} \right) \quad (1)$$

valid for  $a \leq r \leq \infty$ ,  $t \geq 0$ , where  $C = C(r, t)$  = concentration of phosphate for any time 't' at a distance 'r' from the centre of the root;  $D$  = diffusion coefficient;  $a$  = root radius.

As no published data were available concerning the diffusion of phosphate in soil, experiments were carried out to evaluate the diffusion coefficient for Seddon soil using different levels of added phosphate. The techniques described by us elsewhere<sup>7</sup> were used to determine the self-diffusion of <sup>32</sup>P in samples of soil to which  $\text{KH}_2\text{PO}_4$  solution had been added to give phosphate additions ranging from 100 to 2,000  $\mu\text{g P/g}$  soil. The soils were stored at 20 per cent water content for 7 days before the diffusion cells were assembled. The measured diffusion coefficient was calculated from the amount of <sup>32</sup>P transported across the boundary after 6 days' contact. The calculated

diffusion coefficients were very small, ranging from approximately  $2 \times 10^{-10} \text{ cm}^2/\text{sec}$  for the lowest addition to  $4 \times 10^{-8} \text{ cm}^2/\text{sec}$  after addition of 2 mg P/g soil.

Over this range there was a very marked curvilinear relationship between diffusion coefficient and level of phosphate addition, which could be described approximately by:

$$D = KP^2 \quad (2)$$

where  $D$  = measured diffusion coefficient of the phosphate ion in the porous medium;  $K$  = constant;  $P$  = concentration of added phosphate ( $\mu\text{g P/g}$  soil). Since the measured diffusion coefficient is not constant, it is not possible to give a general solution to the diffusion equation (1) given here, but numerical solutions can be obtained for specific initial concentrations and prescribed boundary conditions.

On substituting relation (2) into equation (1) a non-linear equation results which, subject to the imposed boundary conditions, was solved by numerical methods (using an IBM '1620' computer) to give the change in concentration at any point out from the surface of the root with time. Calculations were performed for three levels of added phosphate (150, 300 and 600  $\mu\text{g P/g}$  soil) and two different root dimensions (0.2 and 0.005 mm) corresponding to the observed radii of the main root and the root hairs. Subsequent integration of each set of results around the root axis gave the cumulative change in concentration per unit length of root with time, that is, the mass of phosphate which had moved from the soil to the root surface as a result of diffusion. The mean uptake rates for the different root dimensions at the 3 levels of phosphate are given in the table.

Table 1. PHOSPHATE UPTAKE RATES: COMPUTED AND MEASURED

Computed uptake ( $\mu\text{g P/m/h}$ )	Phosphate addition ( $\mu\text{g P/g}$ soil)		
	150	300	600
For main root	0.074	0.33	1.57
For root hairs	0.0084	0.034	0.13
For proposed model root*	0.494	2.03	7.97
Measured uptake ( $\mu\text{g P/plant/h}$ )	2.7	5.6	12.0
Required length of model root (m/plant)	5.5	2.8	1.5

\* Model root proposed had 50 mm of root hair per mm of main root.

To convert these data to total plant uptake a model of the nutrient-absorbing root must be used. On the basis of microscopic observation of the root systems of wheat plants grown in the Seddon soil (Fig. 1) a model root was adopted, in which every mm of main root has attached to it 50 root hairs, each of an average length of 1 mm, that is, each mm length of root is associated with 50 mm of root hairs. The total uptake rates per unit length of model root for each of the 3 levels of added phosphate are also given in Table 1, together with the mean uptake rate per plant determined in the pot experiment.

By comparing the computed rate of uptake per unit length with the measured uptake rate of the growing plant, the length of model root required to achieve the measured uptake can be calculated, assuming diffusive movement to the root surface were totally responsible. The calculated lengths shown in Table 1 must be recognized as minimum values of actively absorbing root under ideal moisture conditions. The lengths required (2–6 m per plant) are not excessive and may be even less if the root hair numbers or lengths are greater than the estimates used. Field measurements of root lengths of wheat plants indicate values ranging from 32 m (ref. 8) to 0.5 mile (ref. 9) when sown in drills, and up to 50 miles for isolated plants<sup>9</sup>. These suggest that the values

\* Present address: University of Western Australia, Nedlands, Western Australia.

Fig. 1. Photomicrograph of primary root and associated root hairs of a wheat plant grown in Seddon soil after addition of  $150 \mu\text{g P/g}$  soil. Reference line is 0.5 mm

obtained would represent only a small fraction of the total root system.

At maturity the plants in the uptake experiment had a root volume of 7–12 c.c./plant which would correspond to 50–90 m of model root per plant. Fawcett<sup>10</sup> conducted

similar pot experiments and after 6 weeks growth found oven-dry root masses of 0.67 g per plant which would correspond to 15–17 m of model root. At the 6-week stage, the plants would be absorbing phosphate at the mean rate given in the table and so about 40 per cent of the calculated length would need to be active at the lowest P addition or only 7 per cent at the highest level. These results suggest that for the ideal model systems considered, diffusion alone could supply the phosphate absorbed by plants. In practice the conditions are less than ideal, for example, where the water content is less than saturated it is probable that the diffusion coefficient would be lower. On the other hand, it is also likely that older tissue continues to be active in uptake, although perhaps not so efficiently as newer tissue near the root tip.

## THE MOLECULAR PHYSIOLOGY OF CITRATE

By PROF. PAUL A. SRERE

Bio-Medical Division, Lawrence Radiation Laboratory, University of California, Livermore, California

THE term molecular physiology might be applied to those metabolic investigations that relate to the function and control of biological compounds and the reactions they undergo. Thus for a particular substance an investigation of the intracellular and tissue distribution and of the enzymes that catalyse its reactions could yield information on its function. Using this approach, I have reviewed some of the recently reported information on citrate biochemistry in animal tissues.

Citrate has always occupied an important position in metabolism and several recent observations have added new dimensions to its role in living processes. A significant observation was that of Brady and Gurin<sup>1</sup>, who found that the rate of fatty acid synthesis by a crude soluble enzyme system was greatly stimulated by citrate. This observation eventually led to the recognition of three metabolic functions for citrate in addition to its role in the Krebs cycle and ATP production: a source of reducing power, a source of acetyl groups for biosynthetic pathways and a controlling (activating or inhibiting) substance for a number of enzymes.

It is the purpose of this report (1) to review and discuss the data relating to these recently described functions, (2) to present some data concerning enzymes of citrate metabolism in bone, the tissue with the highest citrate content, and (3) to consider several of the problems of citrate metabolism and its control. No attempt will be made to review the literature concerning citrate metabolism in plants and bacteria.

### Metabolic Functions of Citrate

Only four enzymes are known to catalyse chemical conversions of citrate.

In addition, it is useful to consider the NAD-dependent isocitrate dehydrogenase and NADP-dependent isocitrate dehydrogenase as citrate-utilizing enzymes:

Citritase has thus far been found only in bacteria and will not be considered here.

Fig. 1 shows the intracellular distribution of enzymes known to be associated with citrate metabolism in animal tissues. The cytoplasmic citrate-cleavage enzyme is the most recent addition<sup>2</sup>. The occurrence of aconitase both in mitochondria and cytoplasm<sup>3</sup>, as well as the distinction between the mitochondrial NAD-requiring isocitrate dehydrogenase and the cytoplasmic NADP-requiring isocitrate dehydrogenase<sup>4</sup>, are recently accepted ideas. This unique localization pattern for citrate-metabolizing enzymes invites speculation concerning the function of citrate in the cytoplasm.

Let us first consider the evidence and reasoning that support the role of citrate as a hydrogen donor for biosynthetic reactions. The oxidation of citrate in the mitochondria leads to the production of ATP and not to the production of reducing hydrogen available for synthetic purposes. The dehydrogenases coupled to oxidative phosphorylation are NAD-coupled enzymes; once the electrons are transferred to NAD they are transferred in turn to  $\text{O}_2$  with the concomitant formation of ATP. No data are available concerning the transport of NAD(H) or NADP(H) out of mitochondria. Lehninger<sup>5</sup> has shown

Mitochondria	Cytoplasm
Citrate-condensing enzyme	Citrate-cleavage enzyme
Aconitase	Aconitase
NAD isocitrate dehydrogenase	NADP isocitrate dehydrogenase

Fig. 1. Distribution of some enzymes concerned with citrate metabolism

that NADH enters mitochondria very slowly, if at all, unless they are first treated with distilled water with resultant swelling and altered permeability. In addition, Purvis and Lowenstein<sup>6</sup> have shown that nucleotides are transported slowly into mitochondria. Since the reducing potential of mitochondrial metabolism is all converted to ATP and since reductive syntheses usually involve NADPH and occur in the cytoplasm, we must examine the cytoplasm for sources of NADPH. It is doubtful if it can still be claimed that the aconitase or isocitrate dehydrogenase found in the cytoplasm is mitochondrial in origin, so it is probable that these enzymes function to supply hydrogen for cytoplasmic syntheses. Another source of NADPH in the cytoplasm is from the oxidation of glucose-6-phosphate by the enzymes of the so-called 'shunt' pathway<sup>7</sup>.

One cytoplasmic biosynthetic pathway that requires a source of NADPH is the fatty acid synthesizing system. After the work of Brady and Gurin<sup>4</sup> it was shown by several laboratories that other NADPH-generating systems could partially replace the citrate-activating effect on fatty acid biosynthesis. However, in a crude system capable of generating as much NADPH from glucose-6-phosphate as from citrate, six times more fatty acids were made in the presence of citrate than in the presence of glucose-6-phosphate<sup>7,8</sup>. The greater efficiency of the citrate-reducing system may be due to the ability of citrate to activate an enzyme involved in fatty acid synthesis as will be discussed later on.

A second major function for citrate lies in its ability to supply acetyl groups for biosynthetic purposes in a reaction catalysed by the citrate-cleavage enzyme<sup>9</sup>. When the cleavage enzyme was first described<sup>10</sup>, it was believed that it might function as an energetically more economical way of forming citrate. In citrate formation catalysed by the citrate-condensing enzyme reaction, the energy contained in the acetyl-CoA bond is lost, whereas in the reverse of the citrate-cleavage enzyme reaction, the energy of that bond would be conserved as 1 mole of ATP. Later observations<sup>11</sup>, however, showed that though the free energy change for the cleavage reaction was zero, no synthesis of citrate could be detected under a variety of conditions.

The citrate-cleavage enzyme is found exclusively in the cytoplasm, and since it is unable to catalyse the formation of citrate, its function is probably related to its ability to form acetyl-CoA or oxaloacetate<sup>10</sup>. We have pointed out<sup>9,12</sup> that the source of acetyl groups for cytoplasmic syntheses of cholesterol and fatty acids has not been adequately investigated. For the most part, the cell produces its acetyl groups in mitochondria in the reaction catalysed by pyruvate oxidase and utilizes them for syntheses in the cytoplasm. The problem then resolves to the transfer of acetyl groups from mitochondria to cytoplasm. Four possible mechanisms are illustrated in Fig. 2.

The first mechanism shown in Fig. 2 is unlikely; transfer of acetyl-CoA *per se* across the mitochondrial membrane would entail the transport of free CoA back into the mitochondria and, as has already been pointed out here, the available evidence indicates that nucleotide transfer across the mitochondrial membrane is poor. In a discussion on acetyl group transfer, Lowenstein has commented that the rate of diffusion of CoA and its derivatives across the mitochondrial membrane is slow<sup>13</sup>.

The second possibility for acetyl group transfer involves deacylation of acetyl-CoA to acetate, followed by transport of acetate into the cytoplasm where it is reconverted to acetyl-CoA in the reaction catalysed by the cytoplasmic acetate-activating enzyme. The operation of such a mechanism has been suggested by Wieland and Weiss<sup>14</sup>, in connexion with their recent finding that the free acetate concentration of rat liver is 400  $\mu$ moles/g wet weight, 20 times that of acetyl-CoA.

A third possible route of acetyl group transfer is based on the activity of carnitine acetyltransferase: acetyl-CoA in the mitochondria forms acetyl carnitine which is transported into the cytoplasm where cytoplasmic acetyl-CoA is regenerated via the same enzyme<sup>15</sup>. This is an attractive hypothesis because, unlike the second mechanism, it involves no loss of energy. There is good evidence indicating that carnitine acetyltransferase plays a part in the transfer of acetate into mitochondria resulting in increased acetate oxidation on addition of carnitine<sup>16</sup>. Attempts to establish this mechanism as operating in the transfer of acetate out of mitochondria have not been conclusive. We have shown that acetate incorporation into fatty acids *in vitro* can be stimulated by addition of mitochondria<sup>17</sup>. However, when we used an *in vitro* system containing the soluble fatty-acid-synthesizing enzymes and mitochondria to test the effect of carnitine on the incorporation of labelled pyruvate into fatty acids, no effect was observed<sup>18</sup>. On the other hand, Bressler and Katz<sup>19</sup> have reported that the *in vivo* synthesis of long-chain fatty acids by guinea-pig liver and epididymal fat pad from pyruvate-2-<sup>14</sup>C is augmented five- to ten-fold by the feeding of carnitine.

The fourth mechanism illustrated in Fig. 2 is one in which the citrate-condensing enzyme and the citrate-cleavage enzyme act together as an acetyl group carrier. We have pointed out<sup>9</sup> that the function of this system is consistent with the intracellular and tissue distribution of the two enzymes. High concentrations of citrate-cleavage enzyme occur in those tissues that have a high capacity for acetyl group utilization: extracts of rat liver, with a high capacity for fatty acid synthesis, and rat brain, which uses citrate for acetylcholine synthesis, show moderately high specific activities of this enzyme<sup>11</sup>. Recently, Lowenstein's group<sup>20,21</sup> showed that altered nutrition in the rat changes the activity of its citrate-cleavage enzyme in liver and its capacity for fatty acid synthesis in the same direction. Along the same line,

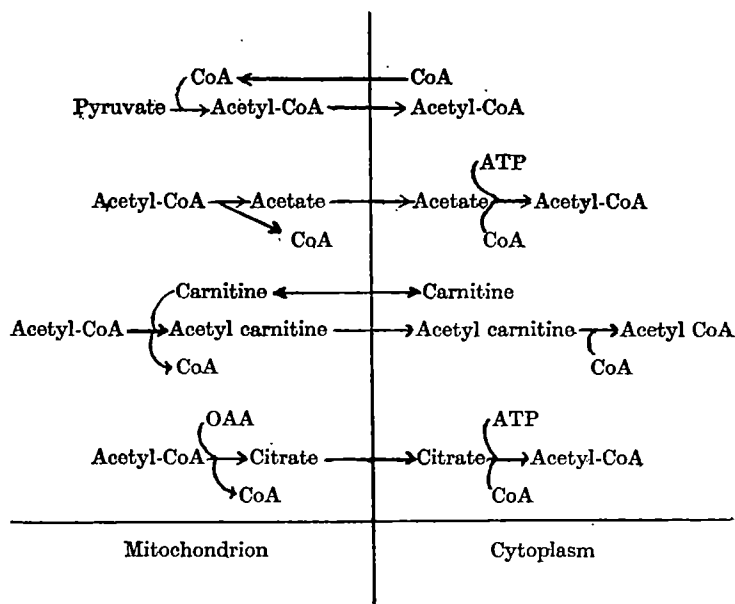

Fig. 2. Schematic representation of four possible mechanisms of acetyl group transfer out of a mitochondrion

Abraham<sup>22</sup>, in an investigation of the lactation cycle of the rat mammary gland, demonstrated that the rate of fatty acid synthesis and activity of the citrate-cleavage enzyme increased and decreased concurrently. Several observations, however, are in contradiction to this hypothesis involving citrate transport for acetyl group transfer. All direct evidence would indicate that the mitochondrial membrane is relatively impermeable to citrate in both directions. Schneider *et al.*<sup>23</sup> showed that the mitochondria contained 70 per cent of the citrate of the cell and that this concentration is not reduced by repeated washing of isolated mitochondria. It is frequently observed that citrate is one of the poorest substrates for mitochondrial oxidation<sup>24</sup>. In experiments in our laboratory no extra-mitochondrial citrate was formed in a system containing labelled pyruvate and pigeon liver mitochondria. Yet citrate does exist in the cytoplasm and some mechanism must place it there—perhaps in some tissues its chief source is from the blood. There is no direct evidence for any of these four mechanisms for transfer of acetyl groups out of mitochondria, and it may well be that all are operative to varying extents depending on the tissue and the physiological state of the animal.

Whatever the mechanism for the transfer of acetyl groups from mitochondria to cytoplasm, it is clear that citrate is as good a precursor for acetyl groups in tissues as is acetate. Lipton and Barron<sup>25</sup> first demonstrated this in experiments in which a crude brain extract catalysed the formation of acetylcholine from citrate, choline, ATP and a yeast factor (CoA). A number of experiments indicate that citrate is an excellent precursor of acetylcholine in brain<sup>26</sup> and in insects<sup>27</sup>. This conversion of citrate to acetylcholine was first thought to be mediated through a reversal of the reaction catalysed by citrate-condensing enzyme, but its requirement for ATP clearly indicates operation of the cytoplasmic citrate-cleavage enzyme in the system. At a suggestion of Dr. Charles West and Dr. Werner Seubert we were able to show that citrate carbon is incorporated rapidly into fatty acids in a pigeon liver system<sup>9</sup>. Similar observations have been reported by several laboratories<sup>28,29</sup>.

Although it has been generally assumed that the conversion of amino-acids such as glutamate to precursors of fat and carbohydrate is mediated by the mitochondrial enzymes of the Krebs cycle, recent data from several laboratories<sup>30-32</sup> indicate that extramitochondrial conversion of glutamate to fat or carbohydrate can occur. The results of isotopic experiments indicate conversion of glutamate to citrate with the subsequent enzymatic cleavage of citrate. By this pathway protein could be converted to fat or carbohydrate without involvement of the Krebs cycle enzyme system. It is interesting to note that the reaction catalysed by the NAD isocitrate dehydrogenase (mitochondrial) cannot be reversed whereas the reaction catalysed by the cytoplasmic NADP isocitrate dehydrogenase is reversible<sup>33</sup>, as is required by the proposed 'reversal' of the Krebs cycle.

The important observation that citrate can act as an activator for acetyl-CoA carboxylase<sup>34</sup> uncovered a third biological role for this compound. Vagelos *et al.* have presented convincing evidence that this activation is attended by a concomitant three-fold increase in the sedimentation coefficient of the enzyme<sup>35</sup>. It is not yet established whether this conformational change represents a physiologically occurring process. It has been reported<sup>36</sup> that tricarballoylate causes trimerization of the carboxylase but no concomitant activation. It is disturbing also that an unusually high concentration of citrate, 0.01 M, is required for activation.

Citrate alters the activity of at least two other enzymes, phosphofructokinase<sup>37,38</sup>, and isocitrate dehydrogenase<sup>36</sup>. The phosphofructokinase reaction is known to be a rate-limiting step in glycolysis, hence this interaction may have important implications in the control of metabolism. Purified phosphofructokinases from a number of sources

are inhibited by citrate. The inhibition occurs at physiological levels of citrate ( $2 \times 10^{-4}$  M) and is reversed by the addition of substrates and other activators of the enzyme. (Since this review was written, a number of reports have appeared that present additional data on the role of citrate in metabolic regulation. The article by J. R. Williamson, E. A. Jones and G. F. Azzone (*Biochem. Biophys. Res. Comm.*, 17, 696; 1964) summarizes this more recent work.) Isocitrate dehydrogenase has been shown to be activated by citrate; the activation is highly specific for citrate<sup>39</sup>.

### Citrate Formation in Bone Tissue

Of all the animal tissues, bone has the highest citrate content<sup>40</sup>. The relationships between bone, citrate and calcium have been intensively investigated and well reviewed<sup>41-45</sup> and will not be discussed at length here. Surprisingly few determinations of citrate-condensing enzyme activity in bone have been made<sup>46-49</sup>. In these the citrate-condensing enzyme activity reported represented the net synthesis of citrate from acetate and oxaloacetate. This net synthesis in turn is a measure of the difference between citrate formation (by an acetyl-CoA-forming system in combination with citrate-condensing enzyme) and the utilization of citrate in the preparations.

Aconitase and isocitrate dehydrogenase activities in various bones were also measured by Dixon and Perkins<sup>46</sup>, but recent work<sup>50</sup> has shown the activity of isocitrate dehydrogenase to be much higher than reported by them. We have, therefore, re-examined the citrate-condensing enzyme of bone using a sensitive enzyme assay method recently developed by us<sup>51</sup>, and we have attempted to measure for the first time the citrate-cleavage enzyme in bone. As can be seen in Table 1, our values for bone citrate-condensing enzyme are two orders of magnitude higher than the values (0.04 units/g) reported by the other workers in this field<sup>46</sup>. The previous work was done with slices of bone or homogenates, which probably explains the low values obtained; citrate-condensing enzyme occurs in the mitochondria, and, as can be seen (Table 2), when a Waring blender is used for more vigorous homogenization, higher activities are obtained. Even the values reported here may be too low since the extraction procedures used here are far from adequate, as can be seen by the low values for protein for shaft extracts. The high activity is even more striking when the relative scarcity of cells in bone compared to soft tissues is considered.

Dixon and Perkins<sup>46</sup> reported that in bone the citrate-condensing enzyme activity (citrate-condensing enzyme and acetate-activating enzyme) was much higher than the isocitrate dehydrogenase activity; they suggested this relationship

Table 1. CONDENSING ENZYME CONTENT OF RABBIT BONE AND MARROW

Bone region	Total protein, mg/g	Condensing enzyme	
		Specific activity, units/mg protein	Total activity, units/g
Tibia end	48	0.06	2.9
Tibia shaft	Not detectable	0	0
Tibia, marrow	30	0.07	2.3
Femur end	15	0.2	2.9
Femur shaft	Not detectable	0	0
Femur, marrow (end)	18	0.1	2.7
Femur, marrow (middle)	30	0.07	2.8

Rabbits were killed by fracture of the cervical vertebrae. Tibias and femurs were dissected from the animal and cleaned of most of the adhering tissue. The bones were then placed in liquid nitrogen. After they were frozen they were broken to give ends and shafts which were separated. The pieces of bone were freed completely of all soft tissue by scraping with a blade. The marrow was removed by washing in a stream of distilled water. In addition, the spongy bone of the ends was cleaned of marrow with a jet of compressed air. Only those shafts which were completely free of spongy bone were used for these analyses. After this cleaning procedure the bone chips were powdered in a mortar, keeping them frozen with liquid nitrogen. When a powder was obtained, an aliquot was weighed into a beaker and about 30 ml. of cold 20 per cent ethanol in 0.4 M potassium chloride per g of femur tissue or marrow (or 10 ml. 0.25 M sucrose for tibia) was added. This mixture was homogenized in an ice-cooled micro attachment to a Waring blender for a total of 5 min. The suspension was centrifuged at 20,000g for 20 min and a portion of the supernatant solution assayed for protein<sup>52</sup>, citrate-condensing enzyme<sup>51</sup>, and citrate-cleavage enzyme<sup>5</sup>. All enzyme units are expressed as  $\mu$ moles of product formed per min at room temperature.

Table 2. COMPARISON OF METHODS OF EXTRACTION OF CITRATE-CONDENSING ENZYME FROM RABBIT FEMUR ENDS

Extraction method	Total protein mg/g	Condensing enzyme specific activity, units/mg protein	Total activity, units/g
Alcohol-KCl (see Table 1) in Waring blender	15	0.2	2.9
0.03 M Tris-HCl-0.013 M Versene pH 8.0+homogenization 4 min in Waring blender	42	0.07	3.0
0.5 M Tris-HCl-0.4 M Versene pH 8.0. Let stand 30 min at 0°	23.3	0.07	1.7

See Table 1 for details.

could account for citrate accumulation in bone. However, later when Van Reen and Losee<sup>60</sup> found high isocitrate dehydrogenase activity in bone, it seemed difficult to explain bone citrate accumulation. A sensible picture is re-established with the values for citrate-condensing enzyme presented here: the citrate-forming capacity now is three times higher than the reported citrate-utilizing activity<sup>60</sup>. It is certainly true that the measurement of enzyme activity usually gives only the maximum enzyme capability for the extract, that is, it does not necessarily indicate the actual rate of tissue synthesis. However, whatever the figures obtained for enzyme activities, it is logical to assume that bone must have higher citrate formation than citrate utilization, since in this tissue the arterio-venous difference for citrate is positive and citrate accumulation is very high.

Very little citrate-cleavage enzyme was detected in bone tissue, a finding consistent with the idea that bone metabolism accounts for a net production of citrate. Citrate-cleavage enzyme is more unstable than the condensing enzyme and it is possible it was destroyed during the extraction, although a similar procedure was used without difficulty to measure the citrate-cleavage enzyme in a number of other tissues. Cleavage enzyme activity of less than 0.05 units/g would not have been detected by our methods; in one experiment we tested a more concentrated homogenate of bone marrow and found 0.03 units/g wet weight marrow.

Table 3. FATTY ACID SYNTHESIS BY BONE MARROW

Substrate	Additions	Fatty acids, total c.p.m.
Acetate 1- <sup>14</sup> C, 1 $\mu$ mole ( $5.0 \times 10^6$ c.p.m.)	—	23,500
Acetate 1- <sup>14</sup> C, 1 $\mu$ mole ( $5.0 \times 10^6$ c.p.m.)	Citrate, 10 $\mu$ moles	50,000
Citrate 1, 5- <sup>14</sup> C, 2.3 $\mu$ moles ( $5.3 \times 10^6$ c.p.m.)	—	2,000
Citrate 1, 5- <sup>14</sup> C, 2.3 $\mu$ moles ( $5.3 \times 10^6$ c.p.m.)	ATP, 5 $\mu$ moles CoA, 0.5 $\mu$ moles	1,800

Marrow from the femur and tibia of a rabbit was homogenized in a Potter-Elvehjem homogenizer in 3 volumes of Gurin's buffer<sup>1</sup>. The homogenate was centrifuged for 20 min at 30,000g and the residue discarded. Each tube contained 0.6 ml. of this supernatant fraction and the additions shown in a total volume of 0.75 ml. Incubations were for 1 h at room temperature. Fatty acids were isolated and counted as described previously<sup>12</sup>.

I found that although bone marrow can make fatty acids from acetate, as reported previously by Altman *et al.*<sup>63</sup>, it is unable to utilize citrate, a finding consistent with its low citrate-cleavage enzyme activity (Table 3). The results reported here differ in two ways from those of fatty acid synthesis in homogenates of liver. First, addition of citrate results in only a two-fold stimulation of acetate incorporation into fatty acids, whereas in liver the requirement for citrate is absolute. Secondly, citrate is a much poorer precursor of fatty acids in marrow than in acetate, whereas the two are about equally effective in liver. This is an apparent exception to the generalization made earlier that high concentrations of citrate-cleavage enzyme are associated with high capacity for acetyl group utilization, and thus seems to support the idea that all possible ways of generating acetyl groups are utilized by cells.

### Control of Citrate Metabolism

The compilation of data from the literature in Table 4 compares citrate, citrate-condensing enzyme and citrate-cleavage enzyme in a number of tissues. Considering that these data represent a collection from various laboratories and that the comparison of such different tissues as liver

and bone on a wet weight basis is difficult at best, I still feel that several relationships deserve to be noticed. These relationships may be fortuitous since the citrate data represent steady-state concentration and the enzyme activities represent maximum capacities. There is a rough correlation between the amount of citrate-condensing enzyme in the soft tissues of a rat and their reported  $Q_{O_2}$  values<sup>60</sup>. This is not surprising since the citrate-condensing enzyme activity represents the first step in the Krebs cycle and the  $Q_{O_2}$  represents the total activity of this pathway. Citrate concentrations in the soft tissues seem to be related to the difference between citrate-condensing enzyme activity and citrate-cleavage enzyme activity. Interestingly enough, when fluoroacetate is injected into animals<sup>60</sup>, then those tissues with high citrate contents and high citrate-condensing enzyme, such as kidney and heart, accumulate most citrate. This probably occurs because those tissues with high condensing enzyme form most fluorocitrate, the compound that inhibits citrate utilization by its inhibitory action on aconitase.

The source of blood citrate is not well known (there is no citrate-condensing enzyme in blood cells), but, according to investigations of arterio-venous citrate differences, it is quite likely that tissues such as intestine and bone and/or bone marrow are able to supply it<sup>45,61</sup>. Similar investigations have indicated that kidney is largely responsible for the utilization of blood citrate<sup>42,61</sup>. No measurements have been reported on the arterio-venous difference for citrate in the heart, but from the data presented in Table 4 one might expect a positive difference.

Table 4. COMPARISON OF CITRATE, CITRATE-CONDENSING ENZYME AND CITRATE-CLEAVAGE ENZYME OF SOME RAT AND RABBIT TISSUES

Species	Tissue	Citrate $\mu$ moles/g	Ref.	Citrate-condensing enzyme, units/g	Citrate-cleavage enzyme, units/g
Rabbit	Liver	0.15	40	2.0	0.10
	Kidney	0.31	40	13	0.23
	Heart	—	—	40	0.22
	Bone (end)	3.5	54	2.9	<0.05
Rat	Liver	0.15	37, 55	5.6	0.67
	Kidney	0.23	56	13	0.97
	Heart	0.39	54, 55	78	0.07
	Bone (end)	2.0	55, 57	1.5	<0.05

The references indicate the sources of the citrate data. Where several values exist, averages were taken and corrected to wet weight values. The citrate-condensing enzyme values were taken from ref. 58 and corrected to rates obtained with our new assay<sup>41</sup>. Citrate-cleavage activities were taken from ref. 2.

The citrate-levels of blood and tissues seem to be under a variety of controls. Administration of vitamin D is known to increase the citrate content of bone, serum and other tissues, and a deficiency of this vitamin results in lowering of citrate-levels<sup>40,62,63</sup>. Hydrocortisone and other steroids can partially reverse the effect of vitamin D<sup>64</sup> and parathyroid hormone has been claimed to reduce citrate-condensing enzyme of bone<sup>57</sup>. Earlier claims of increased citrate formation by bone after administration of vitamin D (ref. 47) or parathyroid<sup>67</sup> are now in dispute, since recent work has demonstrated that vitamin D decreases the utilization of citrate by kidney mitochondria<sup>65</sup>.

Increases in fat metabolism or fatty acid concentration, such as can be caused by fasting or diabetes, result in large increases in tissue citrate-levels<sup>37</sup>. The observation that palmityl-CoA inhibits citrate-condensing enzyme<sup>66,67</sup> gave rise to the suggestion that this interaction might serve as a control of citrate levels in tissues<sup>67</sup>. We have shown, however, that the interaction between citrate-condensing enzyme and palmityl CoA is not a specific one<sup>68,69</sup>, and we have pointed out that the result would be changes in citrate-levels opposite to those observed under various physiological conditions<sup>37</sup>. There is no clear evidence as yet which makes it possible to formulate molecular mechanisms that can account for changes in citrate concentration in animal tissues.

Finally, the ability of citrate to chelate metal ions is well known: it has a relatively high affinity for such cations as  $\text{Ca}^{++}$ ,  $\text{Sr}^{++}$ ,  $\text{Mn}^{++}$ ,  $\text{Mg}^{++}$  and  $\text{Fe}^{+++70}$ . There is little direct evidence relating this ability to metabolic function. It has been shown that Fe citrate is an excellent substrate in the metabolism of Fe transferrin<sup>71</sup>. It is possible that the demonstrated accumulation of  $\text{Ca}^{++}$  by mitochondria may involve citrate metabolism. The binding capacity of citrate for calcium has led to speculations that both the resorption and the formation of bone may involve the chelation of calcium by citrate. It is interesting that citrate has been shown to function better than most chelators in the removal of radioisotopes from bone<sup>72</sup>, and that animals the citrate-levels of which were increased by fluoroacetate treatment excreted more lead than untreated animals<sup>73</sup>.

### Conclusions

This brief synopsis of citrate metabolism is intended to illustrate the unique features of this compound and the surprising diversity of parts it can play in animal tissues. It is difficult to understand the significance of this multiplicity of function and control. Born<sup>74</sup> has said that remarkable scientific achievements have come from "the method of simplifying thought by stressing one aspect only of the facts". None the less, in biological investigations we must deal with systems that are exceptionally complex and we run the danger of choosing model systems that are too simple to advance our understanding. To understand cellular metabolism we must continually search for model systems the complexity of which approaches as closely as possible that of the cell. The models also should have been sufficiently examined to enable us to make some simple predictions and explanations of the more complex cellular systems.

One such model which may prove to be valuable in discussing and understanding metabolic control and regulation is that which has been developed in the field of information theory for the construction of automata. Workers in this field have shown that it is possible to construct reliable circuits, that is, those capable of reliable computation, from unreliable formalized 'neurones' if the network contains sufficient redundancy<sup>75-77</sup>. When we are confronted with a compound such as citrate which is apparently multifunctional and under a variety of controls, or when we consider which of the many available pathways is responsible for acetyl group transfer across mitochondrial membranes, we may do understanding a grave disservice by looking for 'the' function, or control, or rate-limiting step. This diversity of roles for compounds, these multiple controls and pathways, may represent a biological systems redundancy which is necessary for stable metabolic regulation.

This work was performed under the auspices of the U.S. Atomic Energy Commission. I thank Jean Senkin for her assistance in obtaining the bone enzyme data.

## DEXTRAN TURBIDITY: ACUTE DISTRESS-PHASE REACTION

By DR. W. J. FESSEL

University of California School of Medicine, San Francisco, California

DEXTRAN, a glucose polymer synthesized by various organisms, is well known to form complexes with blood proteins. The  $\alpha$ - and  $\beta$ -lipoproteins and fibrinogen are particularly readily bound to dextran, but almost all the blood proteins have been described as binding with it in some degree<sup>1-4</sup>. Besides reacting chemically with dextran, serum may also react with it immunologically. Kabat and Berg<sup>5</sup>, Grabar<sup>6</sup>, Jacobsson and Wikström<sup>7</sup>, and Jacobsson and Zsiga<sup>8</sup> all observed that a small number of normal human sera contained precipitating antibodies to dextran. It has been shown that dextrans may cross-react with several bacterial antisera. These sundry ways of interaction between dextran and plasma are increased in psychiatric patients by the possibility of a reaction between dextran and psychotropic drugs<sup>9</sup>.

A chance observation in this laboratory showed heavy turbidity in the plasma of an acute schizophrenic patient after addition of dextran. Further investigation of this phenomenon showed that: (a) most human plasmas contain measurable amounts of dextran-precipitable material; (b) its mean level is significantly higher in patients with mental disorders than in control subjects; (c) it tends to be more pronounced in patients with the most intense acute symptoms; (d) it increases in response to emotional stress; and (e) the precipitate contains cryoglobulins and cryoprecipitins of more than one sort.

Groups of mentally ill in-patients were investigated at the Langley Porter Neuropsychiatric Institute (LPNI), Veterans Administration Hospital, Palo Alto (VAPA), Napa State Hospital (NSH), Agnews State Hospital (ASH), and San Francisco General Hospital (SFGH). Various personnel from the wards, laboratories and offices at the five institutions provided control groups. Each patient group was compared with the controls from the same hospital. The effects of emotional stress were investigated by examining plasma taken from a group of prisoners on the morning that they appeared before a Parole Board and again two weeks later.

Plasma was obtained from 10 ml. of blood which had been anticoagulated with 2 ml. citrate solution. A 6 per cent solution of dextran in 0.9 per cent saline was obtained from Cutter Laboratories, Berkeley; the primary source Pharmacia, Ltd., Sweden, who had synthesized the dextran from *Leuconostoc mesenteroides*, strain 'NNRL B512'. The dextran used had an average molecular weight of 75,000 with a lower limit of 25,000 and an upper limit of 200,000. Plasma and dextran were mixed and left overnight at 4° C. The precipitate which developed was thoroughly dispersed in a Vortex mixer and the optical density of the plasma was measured at 600 m $\mu$  in a Coleman spectrophotometer; the turbid mixture was then centrifuged and the optical density of the supernatant was re-measured in the same cuvette. The difference in the optical densities before and after centrifugation was taken as the measure of the precipitate. Most of the experiments reported here used a plasma : dextran ratio of 1 : 1 and gave results shown in Table 1. Later experiments used a plasma : dextran ratio of 1 : 2.5. As indicated in Fig. 1, the amount of precipitate is not stoichiometrically related to the amount of dextran added; a plasma : dextran ratio of 1 : 2.5 gave generally higher values.

Electrophoresis, immunoelectrophoresis, ultracentrifugation and immuno-diffusion investigations were made with standard techniques. The Mann-Whitney U test

Table 1. DEXTRAN TURBIDITY TEST IN DIFFERENT MENTAL HOSPITALS

Hospital	No.	Patients		No.	Controls		P
		Mean	S.E.		Mean	S.E.	
LPNI	82	129	15.9	47	76	9.3	< 0.05
VAPA	27	183	23.7	32	85	18.6	< 0.05
SFGH	41	139	22.8	29	90	13.2	0.05
NSH (1)	26	152	18.6	10	97	25.0	< 0.05
NSH (2)	33	211	20.6	20	194	28.0	

Table 2. DEXTRAN TURBIDITY STUDIES AT AGNEWS STATE HOSPITAL

	No.	Mean	P
Controls	17	204	0.08
Short-term drugs*	18	242	< 0.05
Long-term drugs*	20	192	< 0.05
No drugs	13	256	< 0.05

\* See text for definition of short-term and long-term drug therapy.

was used for the statistical analyses; the confidence-level was set at 0.05.

At all five hospitals the mean level of dextran turbidity was higher in the patients than in the controls (Tables 1 and 2). The difference was significant ( $P \leq 0.05$ ) except in the second group of patients and controls tested at NSH. A re-test again showed no difference, a result which cannot be easily explained except by postulating that the ward personnel used as controls were under unusually severe stress. The results in all groups of patients and controls showed considerable overlap.

The following evidence shows that the level of intensity of the symptoms is an important correlate of the level of dextran turbidity in mental disease. The patients were divided into groups according to the duration and amount of dosage of phenothiazine drugs; a short time was taken as less than 2 months and a low dose as less than 400 mg chlorpromazine or its approximate equivalent dose of other phenothiazines. Patients treated for a short time had higher levels of dextran turbidity than patients treated for a long time. This difference was statistically significant at VAPA and ASH, and approached significance at NSH ( $P = 0.06$ ) and LPNI ( $P = 0.08$ ). All the patients

Fig. 1. Curves obtained from two subjects by adding increasing volumes of dextran to one volume of plasma

at SFGH were acutely ill and their blood was tested within a few days of admission; their mean level was significantly higher than in the controls. Subjects treated for a short time with a high dose, that is, those whose symptoms were acute and were also the most florid, had consistently higher mean levels than those treated for a long time with a high dose. These differences were marked: at VAPA 266 cf. 87 ( $P < 0.05$ ); at ASH 242 cf. 192 ( $P < 0.05$ ); at NSH 175 cf. 111 ( $P = 0.06$ ); and at LPNI 190 cf. 102 ( $P = 0.1$ ). In 9 patients at LPNI who were acutely ill, the mean level of turbidity was 233; three weeks later when the general intensity of symptoms had fallen, the mean level of turbidity was 137 ( $P < 0.05$ ).

The medication itself was not directly linked with the amount of dextran turbidity because: (a) patients on high doses of phenothiazines for a long period had consistently lower mean levels of turbidity than patients taking either high or low doses for a short time; (b) at SFGH, where the patients had been given either no tranquillizing drugs or only one or two small, sedating doses, the patients had significantly higher mean levels than the controls; and (c) at ASH, patients who had never had phenothiazines or had not been given them for several months had much higher mean levels than controls.

The high levels were not specific for any particular diagnostic category of mental disease, whether psychotic or psychoneurotic, functional or organic, nor were they specific to mental disease itself. So far, however, higher levels have been seen in mental disease than in most patients hospitalized with acute infections or with severe connective tissue diseases. Age and sex, both factors known to influence some serum proteins, did not seem to affect this reaction.

Emotional stress seems to be an important correlate of the amount of dextran turbidity. The level of turbidity fell in each of eighteen prisoners when plasma taken two weeks after a Parole Board hearing was compared with plasma taken on the morning of the hearing. The mean fall in the dextran turbidity of these plasmas was 66 per cent. Preliminary results in a few rats given repeated small electric shocks to the feet show that this stress causes a considerable rise in dextran turbidity over baseline values.

The wide variation of the values within all groups of patients and controls (Table 1) deserves comment. This was probably not a methodological error. For one plasma examined ten times, the mean value was 115 and the standard error of the mean 1.84. The wide variance in the subject groups was probably due to several substances being precipitated and also to an unfavourable ratio of dextran: plasma. When this ratio was changed from 1:1 to 2.5:1 the variance was lowered; as indicated in Fig. 1 this increased proportion of dextran causes maximal turbidity. We prefer to use this ratio in present-day investigations. The difficulties of reproducing turbidimetric estimations are well known. Yet the reproducibility was not improved after converting the reaction to a colorimetric one by washing the precipitate, dissolving it in 9 M urea and adding Biuret reagent. Seven plasmas were examined both in this way and, at the same time, turbidimetrically; a dextran: plasma ratio of 2.5:1 was used. The coefficient of variation (standard deviation divided by the mean) was 0.49 for the colorimetric method and 0.42 for the turbidity method.

Electrophoretic and ultracentrifugal investigations of a few plasmas showed that 19S protein levels were 38 per cent higher and 7S levels were 11 per cent higher in patients with very high levels of dextran turbidity than in patients with very low levels. There were no clear differences in the electrophoresis results in the two groups. Zone electrophoresis of proteins recoverable from the precipitate showed a single band in the  $\beta$ - $\gamma$  region with a marked trail from the origin. Ultracentrifugation showed that about two-thirds of the material was 7S class protein and the remainder 16S class protein; the exact proportions

are meaningless because of material lost during the purification procedure. Immuno-diffusion in agar investigations showed a strong precipitin reaction with a fibrinogen antiserum, a moderately strong reaction with a 7S antiserum, and a faint reaction with a  $\beta$ -2 macroglobulin antiserum. There were no precipitins formed with antisera to albumin;  $\alpha$ -2 macroglobulin; ceruloplasmin; Cohn's fractions III; Cohn's fractions IV, 5 + 6;  $\beta$ -2A; or  $\beta$ -lipoprotein.

A large proportion of the precipitable material was clearly fibrinogen: (a) there was a strong reaction between the proteins solubilized from the precipitate and a fibrinogen antiserum; (b) the precipitate was more intense in plasma than in serum—in 16 subjects whose plasma and sera were tested simultaneously, the mean serum level was only 26.4 per cent of the mean plasma level. The 16S material in the ultracentrifuge was probably largely polymerized fibrinogen; the 7S material was probably the serum component. The positive reactions in the immuno-diffusion investigations between the isolated precipitate and antisera against fibrinogen and 7S globulin showed immunological non-identity. It is known that dextran forms complexes with fibrinogen; (c) some of this fibrinogen could represent the portion described by Thomas, Smith and Von Korff<sup>10</sup> as cold precipitable in the presence of heparin. However, parallel investigations on 14 normal plasmas using both heparin, 0.1 mg per ml. blood, and dextran as precipitants showed a mean level of 65.7 precipitated by dextran and only 6.9 precipitated by heparin.

The presence of so much fibrinogen in the precipitate suggests the possibility that the increased levels of dextran turbidity in mental disease and emotional stress result from activation of various serum enzyme systems which cause changes in the internal structure of blood proteins. Plasmin, which affects the fibrinogen molecule, is activated by various agents including emotional stress<sup>11-13</sup>, physical stress<sup>14</sup>, adrenal steroids, adrenaline, acetylcholine and histamine<sup>15,16</sup>, and some evidence suggests that plasmin may be under reflex control<sup>17</sup>. Other serum enzymes are also activated by stress, which is known to influence a variety of blood proteins<sup>18</sup>.

Some of the precipitate might represent naturally occurring antibodies to dextran, reported to be present in small amounts in many human sera by Kabat and Berg<sup>5</sup> and Grabar<sup>6</sup>. In two patients, addition of increasing quantities of dextran to constant volumes of plasma caused precipitation in amounts resembling the classical precipitin curves for antigen-antibody reactions (Fig. 1). In both subjects, maximum precipitation occurred with a plasma: dextran ratio of 1:2.5 and increasing the proportion of dextran beyond this caused a decrease in the amount of precipitate.

The possibility of a cross-reaction between dextran and antibodies to bacteria, such as reported by Sugg and Hehre<sup>19</sup> and Neill and Abrahams<sup>20</sup>, was investigated by absorbing two plasmas with various antigens derived from *E. coli*, *Salmonella* and *Streptococcus* (Difco Laboratories). In one plasma there was a 52 per cent reduction in dextran turbidity after absorption with *E. coli* 'O' antigen 026. This is being further examined.

The dextran turbidity reaction provides a simple test which tends to give high values in states of mental distress. The complex reaction depends mainly on formation of precipitates between dextran and fibrinogen with contributions from other globulins. In mental illness, the reaction seems to be related to the level of intensity of the symptoms rather than merely to their severity. The amount of dextran turbidity is likely to be highest in the turbulent state of acute psychotic reactions or during chronic disease when the symptoms have shifted in intensity and have become more florid. The phenomenon is not restricted to any particular sort of mental disorder and seems analogous to the non-specific acute-phase reactants seen in systemic medical diseases.

Various non-specific stresses can affect blood proteins<sup>18</sup>; the preliminary findings suggest that the dextran turbidity reaction may be a non-specific one to any sort of emotional turmoil or stress. It seems likely that the increased levels in mental disease may result from the effects of stress on serum proteolytic enzyme systems which affect the internal structure of various plasma proteins including fibrinogen. The dissection of the components of this reaction might be an interesting avenue of research into mental illness.

## SPARSOMYCIN MODIFICATION OF THE LETHAL ACTION OF IONIZING IRRADIATION ON *Escherichia coli*

By DR. ROBERT F. PITTILO, MARY LUCAS, CAROLYN WOOLLEY, ROBERT T. BLACKWELL and CAROLYN MONCRIEF

Kettering-Meyer Laboratory, Southern Research Institute, Birmingham, Alabama

SPARSOMYCIN ( $C_{13}H_{21}N_3O_6S_2$ ) is an antibiotic of unknown structure<sup>1</sup> which has been reported to inhibit the growth of a variety of micro-organisms, *KB* cells in culture, and transplantable mammalian neoplasms in rodents<sup>2</sup>. In *Escherichia coli*, sparsomycin has been found to inhibit protein synthesis<sup>3</sup>. During the course of routine screening for irradiation modifiers, sparsomycin was found to protect slightly (at low concentrations) and to potentiate markedly (at high concentrations) the lethal action of ionizing irradiation on non-proliferating cell suspensions of *E. coli*.

*Escherichia coli* 'ATCC 9637' was used in most experiments. Stock cultures were maintained, inocula prepared and experiments performed in the following medium:  $NH_4Cl$ , 1.0 g;  $K_2HPO_4$ , 7.32 g;  $KH_2PO_4$ , 3.0 g;  $MgSO_4$ , 0.12 g; deionized water, 1 litre (after autoclaving at 15 lb. pressure for 30 min, 8 ml. of sterile 50 per cent glucose was added). For inocula, cultures were grown at 37° C for 18 h, washed three times in M/15 phosphate buffer (pH 7.0) and standardized to a reading of 0.48 optical density in a Bausch and Lomb 'Spectronic 20' spectrophotometer (660 mμ) with the buffer. Such suspensions usually contain approximately  $5 \times 10^8$  viable cell/ml.

In some experiments the following wild-type cultures of *E. coli* and derived resistant strains were used: *E. coli* 'B' (ORNL) and the derived irradiation-resistant strain designated *E. coli* 'B/r' (ref. 4); *E. coli* 'B' (Hill) and the derived strain of increased irradiation sensitivity<sup>5</sup> designated *E. coli* 'B<sub>s</sub>' (Hill) (these four cultures were kindly supplied by Dr. H. Adler, Oak Ridge National Laboratories); a strain from *E. coli* 'B' (Hill) as resistant to the alkylating agent, 1,3-bis(2-chloroethyl)-1-nitrosourea, and cross-resistant to ionizing irradiation<sup>6</sup>; the wild-type 'B' strain, *E. coli* 'ATCC 11303'; and five strains derived from *E. coli* 'ATCC 9637' which are individually resistant to nitrogen mustard, azaserine, 6-diazo-5-oxo-1-nor-leucine<sup>7</sup>, 2-fluoroadenine and 2-fluoroadenosine<sup>8</sup>.

The procedures used to determine irradiation-modifying activity were: for measuring effects on non-growing cells, washed cell suspensions of 5 ml. were exposed to irradiation from a cobalt-60 source with and without test compound. In most experiments duplicate samples were simultaneously handled. Following irradiation, the cells were suitably diluted in saline and 1-ml. aliquots of appropriate dilutions plated in triplicate. For measuring

effects on growing cells, cells were inoculated into the synthetic medium with and without various concentrations of sparsomycin and aliquots were irradiated immediately after inoculation and after 4 h growth. A second series of tubes was prepared in which the cells were allowed to grow for 4 h, sparsomycin was added, and aliquots were irradiated immediately and again after an additional 2 h growth in the presence of sparsomycin.

Irradiation was accomplished with the use of a flux-loaded <sup>60</sup>Co source (c. 1,000 c.) at a rate of 2.0 kr./min under our conditions of exposure. Tubes of cell suspensions were randomly placed in a circular device which rotates around the source. The tube holder is so constructed that each tube also rotates independently but at a constant known rate during the irradiation-exposure period. Ferric sulphate dosimetry showed constant exposure along the longitudinal axis of the tubes of cell suspensions.

A typical experiment showing modification of irradiation damage in non-proliferating *E. coli* by sparsomycin is presented graphically in Fig. 1. Concentrations of sparsomycin of 3–10 μg/ml. appear to protect slightly against irradiation damage. Thirty μg/ml. is essentially without effect and higher concentrations (100–1,000 μg/ml.) markedly potentiate irradiation damage. The protection afforded by low concentrations of sparsomycin is slight but consistent. In four individual experiments the observed protection falls beyond one standard deviation from the control-kill value.

The effect of sparsomycin on irradiation damage of several cultures of non-proliferating *E. coli* and derived resistant strains is summarized in Table 1. Sparsomycin, 10 μg/ml., slightly protects *E. coli* 'ATCC 9637', *E. coli* 'B' (Hill) and *E. coli* 'B ATCC 11303' against irradiation damage. Sparsomycin, 10 μg/ml., does not influence the response of *E. coli* 'B' (ORNL) to irradiation. This same dose of sparsomycin potentiates irradiation damage in the irradiation sensitive strain *E. coli* 'B<sub>s</sub>' (Hill). All the cultures examined were sensitive, in varying degrees, to the irradiation-potentiating effect of 100 μg sparsomycin/ml. Interestingly, cultures resistant to alkylating agents such as nitrogen mustard, azaserine, or 1,3-bis(2-chloroethyl)-1-nitrosourea (BCNU) were much less sensitive to the sparsomycin potentiating effect than were the parent cultures. Similarly, the irradiation-

<i>Escherichia coli</i> 'B', 'ATCC 11303'	0.11	0.415	< 0.0005	0.26	> 220.0
<i>Escherichia coli</i> 'B' (ORNL)	0.167	0.153	< 0.00067	1.09	> 249.25
<i>Escherichia coli</i> 'B/r'	34.74	25.26	1.47	1.33	23.63

\* Sparsomycin is non-toxic at these concentrations under test conditions used.

† Resistance to a growth inhibitor indicated thus:

Name of parent culture/name of inhibitor to which strain is resistant.  
 HN<sub>2</sub> = Nitrogen mustard      AZA = Azaserine      r = Radiation  
 FAS = 2-Fluoroadenosine      DON = 6-Diazo-5-oxo-1-norleucine  
 FAD = 2-Fluoroadenine      BCNU = 1,3-bis(2-chloroethyl)-1-nitrosourea

resistant *E. coli* 'B/r' was less sensitive to the sparsomycin-potentiating effect than was its parent culture, *E. coli* 'B' (ORNL). The strain of *E. coli* resistant to the irradiation modifier 2-fluoroadenosine<sup>8</sup> was less sensitive to the sparsomycin potentiating effect than was either the parent culture or a sister culture resistant to the non-radiation modifier, 2-fluoroadenine.

The potentiating effect of sparsomycin is demonstrable over a range of irradiation doses (see Fig. 2). Irradiation kill incurred by doses of 2.5 kr. or lower does not appear to be enhanced by sparsomycin (100  $\mu\text{g}/\text{ml}$ ).

Fig. 1. Sparsomycin modification of the damaging action of ionizing irradiation ( $^{60}\text{Co}$ , 20 kr.) on *Escherichia coli* 'ATCC 9637' (non-proliferating). Horizontal line at c. 0.6 per cent survivors indicates per cent survivors to irradiation kill in the absence of sparsomycin with one standard deviation indicated. P = probability values of observed sparsomycin-irradiation effects

The effect of reported radiation protectors on the irradiation potentiating action of sparsomycin has been investigated. Cysteamine is without detectable effect on the sparsomycin potentiating effect (see Fig. 3). Cysteine<sup>9</sup> appears to protect slightly against the sparsomycin potentiating effect (Fig. 4) under these conditions.

Sparsomycin must be present during the irradiation period in order for its potentiating effect on non-proliferating *E. coli* to be demonstrated. Mixing suspensions of irradiated cells (20 kr.) with separately irradiated (20 kr.) sparsomycin (100  $\mu\text{g}/\text{ml}$ ) resulted in the same percentage survivors as were present in the control irradiated cell suspensions. Additionally, cells which had been suspended in sparsomycin (100  $\mu\text{g}/\text{ml}$ ) for 1 h, washed three times

Fig. 2. The effect of irradiation dose on sparsomycin modification of irradiation damage in *Escherichia coli* 'ATCC 9637' (non-proliferating)

Fig. 3. The effect of cysteamine (0.77 mg/ml.) on the potentiation by sparsomycin of irradiation damage in non-proliferating cell suspensions of *Escherichia coli* 'ATCC 9637'

Fig. 4. The effect of cysteine (1.2 mg/ml.) on the potentiation by sparsomycin of irradiation damage in non-proliferating cell suspensions of *Escherichia coli* 'ATCC 9637'

by centrifugation and irradiated (20 kr.) were no more sensitive to irradiation than were control cells. Lastly, cells grown in non-toxic or partially toxic concentrations of sparsomycin (1 and 10  $\mu$ g/ml., respectively) were no more sensitive to irradiation when tested in buffer suspensions than were control cells.

Furthermore, an interesting sparsomycin-cysteine relationship has been observed: suspensions of irradiated cells (20 kr.) were very sensitive to a solution of cysteine (1.2 mg/ml.) and sparsomycin (0.1 mg/ml.) which had been separately irradiated (20 kr.). This solution was non-toxic to unirradiated cells. An unirradiated solution

of these two materials was non-toxic to both irradiated and unirradiated cells of *E. coli* (see Table 2). In experiments with growing cell (*E. coli* 'ATCC 9637') no effect by sparsomycin at non-toxic or partially toxic concentrations on irradiation damage has been observed.

As a potentiator of irradiation kill of non-proliferating *E. coli* cells suspended in buffer, sparsomycin is similar to chloral hydrate<sup>10</sup>, 2-fluoroadenosine<sup>8</sup>, and many other potentiators which must be present during the irradiation period and require moderately damaging doses of ionizing irradiation for the potentiating action to be observed. The decreased sensitivity to the sparsomycin potentiating action of strains of bacteria resistant to alkylating agents or ionizing irradiation is in agreement with earlier investigations with the radiation potentiator hadacidin<sup>11</sup> as well as with previously reported cross-resistance interrelationships between alkylating agents and irradiation in *E. coli*<sup>6,12,13</sup>.

The slight irradiation protection afforded by low concentrations of sparsomycin is obviously not clearly understandable. However, sparsomycin does contain sulphur in its structure. The observation that sparsomycin irradiated in the presence of cysteine yields a toxic product suggests the possibility that the sparsomycin structure is altered during irradiation. It may be noted that sparsomycin solutions following irradiation yield an odour similar to some sulphides.

The antibiotic sparsomycin demonstrates slight irradiation-protecting activity at low concentrations (10  $\mu$ g/ml.) and marked irradiation-potentiating activity at higher concentrations (100  $\mu$ g/ml.) in several strains of non-proliferating *E. coli*. Sparsomycin must be present during the irradiation period in order for the potentiating effect to be demonstrated. A dose of ionizing irradiation which in itself is not appreciably lethal for non-proliferating *E. coli* is not potentiated by sparsomycin. Strains of *E. coli* resistant to alkylating agents or ionizing irradiation are less sensitive to the sparsomycin potentiating effect than are the parent cultures from which they are derived.

Table 2. THE EFFECT OF SPARSOMYCIN AND CYSTEINE ON THE LETHAL ACTION OF IONIZING IRRADIATION ON SUSPENSIONS OF *Escherichia coli* 'ATCC 9637'

Effect of sparsomycin, cysteine, and sparsomycin + cysteine, irradiated and non-irradiated, on non-irradiated *Escherichia coli*

Compound(s)	% Survivors to irradiated compound(s)	% Survivors to non-irradiated compound(s)
Sparsomycin, 0.1 mg/ml.	97-92	98-96
Cysteine, 1.2 mg/ml.	101-00	101-04
Sparsomycin, 0.1 mg/ml. + cysteine, 1.2 mg/ml.	95-83	102-08

Effect of sparsomycin, cysteine, and sparsomycin + cysteine, irradiated and non-irradiated, on irradiated *Escherichia coli*

Compound(s)	% Survivors Cells and compound(s) irradiated separately, then combined	% Survivors Cells and compound(s) irradiated together
Control	0-36	—
Sparsomycin 0.1 mg/ml. Non-irradiated	0-125	—
Cysteine, 1.2 mg/ml. Non-irradiated	0-58	—
Sparsomycin, 0.1 mg/ml. + cysteine, 1.2 mg/ml. Non-irradiated	0-21	—
Sparsomycin, 0.1 mg/ml. Irradiated	0-135	< 0-001
Cysteine, 1.2 mg/ml. Irradiated	0-41	54-16
Sparsomycin, 0.1 mg/ml. + cysteine, 1.2 mg/ml. Irradiated	< 0-001	15-62

Preliminary data are given which suggest that sparsomycin in the presence of cysteine on irradiation yields a material toxic for irradiated *E. coli*. The radiation modifying effect of sparsomycin has not been observed in rapidly dividing *E. coli* cells.

We thank Dr. Frank M. Schabel, jun., for his advice, and Mr. Edward Bannister, Mr. Carl W. Davis and Miss Mary Virginia Wright for their help.

## COMPLEMENT-FIXATION TESTS IN TOXOPLASMOSIS WITH PURIFIED ANTIGEN

By DR. J. D. FULTON and PROF. FORREST FULTON

London School of Hygiene and Tropical Medicine, Keppel Street, London

THE complement-fixation test was first used in the diagnosis of toxoplasmosis<sup>1</sup>. The authors used as antigen the extracts of brain and spleen of infected rabbits. Since then a variety of other impure antigens has been used in the test and in consequence it has not been possible to compare results obtained in different laboratories. A pure suspension of *Toxoplasma gondii*, free from other cells, was used in this test<sup>2</sup>. The antigen has now been standardized by counting the parasites or by determination of the optical density of the suspension. Also, on freeze-drying the material in dextran it has been found that the properties of the antigen for complement fixation remain unimpaired. Some comparisons have been made of the results obtained by this method, by the dye test<sup>3</sup> and by the direct agglutination test<sup>4</sup>.

**Antigen.** This was obtained from the peritoneal exudate of cotton rats infected with the RH strain of *Toxoplasma gondii*. The nature of the preparation is shown in Fig. 1. It was treated with 1 per cent formalin in saline for 24 h, which was then replaced with a 1/10,000 solution of this substance or of merthiolate. The antigen used in the present experiments had  $7.5 \times 10^8$  parasites per ml. of suspension and its optical density in a Hilger Biochem absorptiometer using an Ilford filter RO 2 and 0.5 cm cell was 0.49. Aliquots of the suspension were prepared in

Fig. 1. Suspension of *Toxoplasma gondii* free from other cells, as used in complement-fixation test ( $\times 1,320$ ).

Fig. 2. The unit complement contour. This contour line denotes the antigen-antibody mixtures which fix exactly one unit of complement. Antigen: a purified suspension of *Toxoplasma gondii* containing  $7.5 \times 10^8$  parasites/ml. Antiserum, a known positive human serum. O, Points derived from the antigen contours; ●, points derived from the antiserum contours.

saline and in 6 per cent salt-free dextran. When freeze-dried in 2 ml. amounts and reconstituted by addition of distilled water the dextran mixture gave a satisfactory suspension. The properties of the freeze-dried suspension kept at 4° C were unimpaired when re-tested six months later.

**Complement fixation.** The antigen was used in a three-dimensional complement-fixation test<sup>5</sup> with a known positive serum with overnight primary fixation at 4° C. Antigen and antiserum contours were drawn, and from these contours the unit complement contour was constructed; this contour line denotes the antigen-antibody mixtures which fix exactly one unit of complement (Fig. 2). For a constant antigen, two-dimensional complement-fixation test, a dilution of 1 in 15 of this purified antigen was selected from the optimal range of antigen dilutions which gave a maximum serum titre. It contained  $5 \times 10^7$  parasites per ml. Fifteen human sera were tested using the plate method<sup>6</sup>. One plate ruled

with 100 squares was used for each serum; the design of the test is shown in Table 1. The sera were inactivated at a dilution of 1 in 5 for 0.5 h at 56° C. The row variable on each plate was a set of 9 doubling dilutions of one of the sera starting with a dilution of 1 in 5. The tenth row was a control containing diluent but no serum. The column variable on each plate was a set of four complement dilutions spaced at 0.2 log<sub>10</sub> intervals. The first dilution in the set contained more than one unit of complement and the fourth dilution contained less than one unit. The set in columns 1, 2, 3 and 4 was repeated in columns 6, 7, 8 and 9. The fifth and tenth columns were controls containing diluent but no complement. A drop of diluent was added to each of the 50 squares on the left half of the plate and a drop of the selected antigen dilution was added to each of the 50 squares on the right half of the plate. The right half of the tenth row was the antigen control.

After overnight fixation at 4° C the titres of the sera were defined as the highest dilution which fixed

one unit of complement at the selected antigen concentration.

To test the feasibility of freeze-drying the antigen, a single contour at the selected level (1 in 15) was estimated with a known positive human serum. The contours are shown in Fig. 3.

In Table 2 are shown the titres determined on 15 human sera by the dye test, direct agglutination and by complement fixation.

There is a considerable degree of correlation in the results obtained by the different methods. It is usual to find the titres determined by complement fixation to be lower than those found in the direct agglutination or dye test. The complement-fixation test is more exacting to perform but is capable of a precision not always shared by the other tests. It also has the advantage that the antigen can be preserved by freeze-drying. This is not possible if the dye test is used because the parasites must be viable, and the agglutination test is also impracticable because the suspension of parasites after drying is auto-agglutinable.

Interest in *Toxoplasma gondii* was mainly zoological until 1939 (ref. 7), when it was isolated from children suffering from encephalomyelitis. Congenital and acquired forms of the disease are recognized and the parasitic attack is directed mainly against nervous tissue. Brain cord and eye are most affected in the congenital forms of the disease. Distribution is world-wide, and the interest of the public health authorities is evidenced by the provision of two reference laboratories in the United Kingdom where serological tests for the detection of *Toxoplasma* antibodies are performed.

Many of these tests have been devised and their number suggests that diagnosis of the disease by sero-

logical methods has not yet been perfected. The dye test and the complement-fixation reaction are probably most widely used. In the latter test the antigens have been so variable in origin that the results of tests from laboratories throughout the world could not be compared with any confidence. By the preparation of a pure antigen this difficulty has now been resolved. Further, the antigen can be freeze-dried and reconstituted and lends itself to accurate standardization by parasite counts, by nitrogen content or more simply by optical density measurements under standard conditions. It has been suggested that the World Health Organization should prepare a standardized serum for use throughout the world. It seems to us equally important that a standard antigen should be available for workers in this field, and its preparation is now feasible.

Earlier experiments on the immunization of rabbits with this pure antigen gave rise to a steady increase in the titre of antibody in serum in the direct agglutination and complement-fixation tests, indicating that a true antigen-antibody reaction was taking place. Since it is the same parasite which infects man, the results with human serum should be entirely specific. Although

widespread serological surveys have been carried out among populations in the past, correlation of the results with the clinical picture has been rare. The method of spread of the disease is still obscure and the acute disease is rarely detected except in cases occurring by accident in laboratories and they number less than a dozen. There is widespread occurrence of toxoplasmosis among sheep in Britain and, as in human populations, abortion, premature births and still-births are common. Isolation of the causative organism would be more satisfactory, but a serological test sufficiently sensitive and specific would give valuable information on the true prevalence of toxoplasmosis to-day. International co-operation is a desirable aim.

## THE NEURONE SURFACE

By DR. PATRICIA V. JOHNSTON and DR. BETTY I. ROOTS

Department of Anatomy, University College, London

**R**ECENTLY we observed that isolated neurones lacked the typical electron micrographic image of a plasma membrane, and suggested that if one accepts that the neurone surface constitutes part of a liquid-crystalline phase system it should be possible to develop a medium in which the molecular orientation responsible for the electron dense image of a surface membrane is maintained<sup>1</sup>. The fact that we have now been able to devise such a medium emphasizes the interfacial characteristics of the neurone membrane as distinct from true solid, semi-solid membrane characteristics<sup>2</sup>. Since in this medium neurones are subjected to the same isolation procedure and hence the same mechanical stresses, the alternative view that the neurone membrane is a separable morphological entity appears unlikely. Recently there has been a revival of interest in visualizing cell membranes as part of multiphasic systems<sup>3,4</sup>, but supporting evidence from experiments on cells has hitherto been lacking.

The isolation of neurones in Ringer-Locke solution leads to extensive disruption of the surface, a membrane image being seen only where boutons are present. In the work recorded here, therefore, neurones prepared in Ringer-Locke solution served as the controls. The experimental media used were a 0.9 per cent solution of NaCl, and three solutions containing 0.25 mg, 0.55 mg and 1.1 mg of gangliosides per ml. of 0.9 per cent NaCl respectively. The pH of all media was 7.2-7.4. The first of these media was chosen since it was believed that the absence of bivalent ions would tend to increase the hydration of surface molecules. It has been shown, for example, that calcium ions decrease the water content of phospholipid membrane models<sup>5</sup>. Since the stability of particular liquid-crystalline systems is highly dependent on their degree of hydration, we believed that removal of the neurones from their supporting environment had led to a loss of hydration of surface molecules and a consequent disruption of their orientation. A number of polyanionic molecules were considered as possible constituents of the other media, but the gangliosides were chosen for preliminary investigations since their presence in brain tissues is well established and they have been shown to be involved in ion movements across cell membranes<sup>6</sup>. It is

known that gangliosides interact with inorganic cations<sup>7</sup>; therefore, in order to leave free anionic groups for interaction with neurone surface molecules they were added to the simple medium. The action of individual ganglioside molecules on surfaces may be expected to be at a maximum at the critical micelle concentration (CMC); therefore, the choice of the amounts of gangliosides used was made on the basis of the reported CMC in water and its alteration in NaCl solutions<sup>7</sup>. The gangliosides (a special order from Light-Koch Laboratories, Ltd.) were prepared according to Gammaack<sup>7</sup> and contained 26.5 per cent *N*-acetyl neuraminic acid. On thin-layer chromatography they were resolved into five major bands corresponding to mono-, di-, and tri-sialogangliosides<sup>8</sup>.

Neurones from the lateral vestibular nucleus of ox brain were isolated by the method previously described<sup>1</sup>. Ten to twenty isolated cells were placed in polythene planchets, the medium was withdrawn and the neurones were fixed, embedded, and sectioned for electron microscopy. Several batches of cells were prepared in each medium and most were fixed by osmication, but some were fixed with buffered glutaraldehyde. More than 2,000 sections from 50 neurones selected randomly were examined. The results reported here refer to effects on the soma and dendrite surfaces only. We have observed that the surface structure of the axon hillock and the initial segment of the axon appears to differ from that of the soma and dendrites, and this will be the subject of another communication.

Considerable maintenance of an electron dense surface lamina was achieved, the most striking results being obtained with the media containing 0.55 mg and 1.1 mg gangliosides per ml. 0.9 per cent NaCl. However, the weakest solution of gangliosides, and the 0.9 per cent NaCl alone, gave some retention of the image. In agreement with previous observations<sup>1</sup> all cells prepared in Ringer-Locke solution lacked a membrane image except where boutons remained attached. Fig. 1 shows a typical Ringer-Locke preparation in which the neurofilaments appear to be flying out from the surface. Fig. 2a shows part of the soma of a cell prepared in 0.9 per cent NaCl in which the membrane image is lacking but the surface does not show the complete disarray seen in Fig. 1. Fig.

Fig. 1. Soma surface of cell prepared in Ringer-Locke solution

Fig. 2. Soma surface of cells prepared in 0.9 per cent NaCl. (a) Showing membrane lacking; (b) showing partial retention of membrane

2b also shows part of the soma of a neurone prepared in 0.9 per cent NaCl but one in which there appears to be considerable maintenance of surface structure. This effect was noted in approximately 20 per cent only of the 0.9 per cent NaCl samples. The addition of gangliosides to the media had a pronounced effect on retention of surface molecular orientation. More than 50 per cent of the neurones selected from the weakest ganglioside medium (0.25 mg/ml.), and 80–90 per cent of the cells examined from the stronger ganglioside solutions, showed considerable maintenance of the membrane image. In Figs. 3 and 4 are shown parts of the soma and dendrite surfaces of neurones prepared in 0.55 mg and 1.1 mg gangliosides

per ml. 0.9 per cent NaCl respectively. In general, when the membrane image was maintained it appeared as a continuous dense line 50–80 Å thick (Figs. 3 and 4a). In osmium tetroxide fixed material electron microscopy usually reveals a single dense line 60–80 Å thick at cell

Fig. 3. Soma surface of cell prepared in 0.55 mg gangliosides per ml. 0.9 per cent NaCl

Fig. 4. (a) Soma surface of cell prepared in 1.1 mg gangliosides per ml. 0.9 per cent NaCl; (b) soma surface of cell prepared in 1.1 mg gangliosides per ml. 0.9 per cent NaCl showing precipitation on cytoplasmic side. Inset: membrane of dendrite showing heavy precipitate

surfaces<sup>9</sup>. It has not been possible at this stage to determine whether permanganate fixation would reveal the triple surface structure described by Robertson<sup>10</sup> since it was found that reaction of potassium permanganate with gangliosides led to incomplete fixation. It is hoped to overcome this difficulty in further investigations. In places the surface line was broken or appeared to have 'bubbles', examples of which may be seen in Figs. 3 and 4. In several samples of cells prepared in the strongest ganglioside solution there appeared to be precipitated material on the cytoplasmic side of the membrane (Fig. 4b). This effect was seen most frequently on dendritic surfaces and may indicate a special property of some dendrites. Some of these observations may be explained by variations in the angle between the cell surface and the plane of sectioning. Such effects have been discussed in detail by Goldberg and Green<sup>11</sup> in relation to the sectioning of fibroblasts from tissue cultures. In a number of respects the type of structure seen at the surface of neurones isolated in the presence of gangliosides and fibroblasts from cultures is similar.

The results obtained are indicative of phase phenomena in operation at the neurone surface. The isolated neurones are free from glia and are to a considerable extent stripped of boutons. Thus removed from the influence of the opposing phases containing polyanionic molecules and placed in a medium like Ringer-Löcke containing bivalent ions, the surface molecules of the neurone suffer a loss in hydration and a disruption of their orientation with consequent loss of the electron dense image. In these circumstances the neurones appear to exist in a gel-like state<sup>1</sup>. The isolation of the neurones in the ganglioside solutions simulated the natural opposing phase systems sufficiently well to maintain certain features of the usual membrane image. It may be surprising that the isolation of neurones in the absence of bivalent ions was sufficient to maintain the membrane image in some cases; however, this was anticipated for two reasons. First, during the isolation procedure it is likely that some polyanionic molecules such as gangliosides remain associated with the neurone surface and in the absence of bivalent ions their effect on surface molecules is not completely lost. Furthermore, the absence of calcium may be expected to favour water retention<sup>5</sup>. It may indeed be anticipated that the maintenance of the electron dense image of a surface membrane of any isolated cell or sub-cellular particle will depend largely on the relative affinity of stabilizing polyanionic molecules for the isolated phase. Thus, since gangliosides are concentrated in the nerve endings<sup>12,13</sup> they retain the membrane image on isolation<sup>14</sup>.

It is now possible to visualize how the surface lipoprotein molecules of neurones and their supporting glia and boutons are stabilized as opposing liquid-crystalline phases in such a way that the resultant interface provides the functional basis of an excitable membrane. It appears that the polyanionic gangliosides located predominantly in the nerve endings<sup>12,13</sup> serve two major functions. By virtue of their hydrophilic properties they regulate the degree of hydration of surface molecules and hence the stability of liquid-crystalline phases. Furthermore, they prevent coalescence of the phases by having affinity for both and by providing an interfacial barrier of ionic charges which is enhanced by their ability to interact with cations. Mucopolysaccharides located in the glia may be visualized as serving similar functions. Thus, the phases represented by the electron dense images of the neurone, glia and bouton membranes and the non-electron dense interface together form the functional unit.

The proposed system is endowed with considerable lability since any event which alters the ion- and water-binding states of interfacial polyanions would alter the attractive forces between the long-chain molecules of the lipoproteins in opposing phases, probably their phase form, and the diffusion properties of the system. It is to be expected that the magnitude of the non-electron-dense

interface seen between neurones and their supporting glia and boutons will differ with the composition and tonicity<sup>15</sup> of the preparative and fixative solutions. It follows that we do not support the view that there is appreciable extracellular space or 'gap substance'<sup>16</sup> between neurones and their surrounding elements since the hydrated polyanionic molecules at the interface are visualized as an integral part of the membrane system. Wyckoff and Young<sup>17</sup> by electron microscopy first showed that there are no large spaces or intercellular matrix between nervous elements and they concluded that exchanges between neurones and capillaries probably take place through the glial cytoplasm. On the basis of the present theory it must be concluded that their postulations are correct. Lumsden<sup>18</sup>, Sjöstrand<sup>19</sup>, de Robertis<sup>20</sup>, and Karlsson and Schultz<sup>15</sup> have also reported results and expressed opinions which are in agreement with Wyckoff and Young's original statements.

The complete physiological integrity of the proposed system is undoubtedly dependent on many factors. It is to be expected that the presence of substrates involved in oxidative phosphorylation is intimately involved. The present interpretation of the results is dependent on the physical limits set for the cell surface. If a third phase or 'gap substance' is visualized it may be proposed that the use of media free of calcium or containing calcium chelating agents decreased the adhesion between the opposing 'membranes' of the neurones and their surrounding glia and boutons, thus favouring retention of the neurone membrane. Further investigations designed to clarify this point are in progress. It appears, however, that the role of gangliosides may well be dominant. Several reports on the properties of gangliosides clearly indicate their importance in the control of nervous activity. They appear to be acceptors for serotonin in the central nervous system<sup>21</sup> and have been shown to interact with chlorpromazine<sup>22</sup>. Recently, Burton *et al.*<sup>23</sup> have suggested that gangliosides are involved in the transport of acetylcholine to the pre-synaptic membrane. McIlwain<sup>6</sup> has demonstrated that the action of gangliosides in restoring excitability to isolated cerebral tissues is related to ion movements across cell membranes. The results and hypotheses presented here clarify the mechanisms involved.

We thank Prof. J. Z. Young for his helpful criticism. We also thank Dr. E. G. Gray for his comments on the electron micrographs and Mr. S. Waterman for assistance with photography. This work is supported by a grant from the Nuffield Foundation.

## NEURONE—SATELLITE CELL RELATIONSHIP

By PROF. C. P. WENDELL-SMITH, PROF. M. J. BLUNT, F. BALDWIN and P. B. PAISLEY

School of Anatomy, University of New South Wales, Kensington, N.S.W.

SINCE the first recognition of macroglia as distinct from neurones by Virchow and the first suggestion by Holmgren that these cells are concerned with the metabolic support of neurones, much confirmatory evidence for the latter concept has accumulated. Apart from the intimate cell contacts and membrane relationships revealed by light and electron microscopy, there is morphological and experimental evidence that the number of perikaryal satellite cells is related directly to the functional load imposed on the perikaryon by the maintenance of varying lengths of axon and by nervous activity (see review by Hamberger<sup>1</sup>). Microchemical methods have demonstrated that the perikaryon and its satellite cells are complementary, at rest or in nervous activity, in respect of RNA base composition, RNA and protein content, and enzymatic activity<sup>2</sup>. The results suggest that the perikaryon and its satellite cells form a metabolically linked cyto-physiological unit. However, analysis of this linkage has been hampered by the use of an experimental model with a mixed population of oligodendrocytes and astrocytes. The problem of mixed samples is aggravated by the lack of agreement among electron microscopists on the identification of glia-cell types<sup>3</sup>.

Again, investigations of the neurone-satellite cell relationship are incomplete if only the perikaryon of the neurone is considered. Yet work on the axon and its satellite cells has been limited in range if not quantity. The intimacy of this relationship in peripheral nerve has recently been brought home by the description of paranodal columns of Schwann-cell cytoplasm which are packed with mitochondria<sup>4</sup>, and of highly regular nodal processes of Schwann-cell cytoplasm which have a specific internal structure and end in close apposition to specific reception areas on the unit membrane of the nodal axon<sup>4</sup>. Since the satellite-cell columns contain perhaps sixty times the number of mitochondria in the subjacent axoplasm, they may be an important site for the production of energy-rich compounds. These may be transported to the axonal membrane, via the nodal processes, to provide the energy to drive, for example, the ionic pump-mechanism; the nodal processes may also facilitate interchange of other materials between the satellite-cell cytoplasm and the axon<sup>5</sup>. Whereas the number of satellite cells related to the perikaryon depends on functional considerations<sup>1</sup>, the number of satellite cells related to the axon in myelinated peripheral nerve fibres depends on morphogenetic and growth processes: since the number of satellite cells and internodal segments is determined at the onset on myelination<sup>6</sup>, the effects of functional load on such a fibre may be reflected in the degree of specialization and complexity of its nodal and paranodal apparatus. Biochemical and metabolic investigations of peripheral nerve have seldom considered the role of the satellite cells; results of such investigations have usually been interpreted as intrinsic to axons or to fibres as a whole. However, the enzymatic activities of the sheath and axoplasm of squid giant fibres seem to be complementary<sup>6</sup>. No comparable specific paranodal apparatus or nodal processes have been described in the central nervous system, but again the axon and the satellite cells show complementary enzymatic activity in certain human fibre tracts<sup>7</sup>.

Investigations on the optic nerve head of the cat have cast light on some of these problems. In the cat, as in man, the fibres of the optic nerve appear to be myelinated only behind the lamina cribrosa. In and anterior to the

lamina all the fibres are non-myelinated, as judged by light microscopy. Silver investigations revealed that, whereas the post-laminar part contains both astrocytes and oligodendrocytes, the laminar and prelaminar parts of the nerve contain only astrocytes<sup>8</sup>. This permitted the identification of astrocytes by electron microscopy and the correlation of the ultrastructural and light microscopical characteristics of three glia-cell types<sup>9</sup>. The first type was found in association with non-myelinated fibres in the prelaminar region where it corresponded to the small (spider) astrocyte: its extensive processes and its perikaryon contained abundant closely packed fine fibrils, but other cytoplasmic inclusions were not conspicuous. A second type was found in the immediately prelaminar or laminar regions and corresponded to the typical astrocyte: its ultrastructural characteristics were intermediate between those of the other two types; associated with it were a number of finely myelinated fibres, unrevealed in this situation by light microscopy. A third type was found only in the post-laminar region in association with more-heavily myelinated fibres, and thus corresponded to the oligodendrocyte: neither its smaller and less numerous processes nor its perikaryon contained fibrils; the denser perinuclear cytoplasm was less voluminous, but ribosomes and orientated endoplasmic reticulum were prominent. So far as the fibres were concerned, no specific organized paranodal apparatus was seen outside the myelin sheath. In this respect paranodal or juxta-terminal sections of fibres of the central nervous system<sup>10</sup> resemble those of similar-sized fibres of the peripheral nervous system<sup>11</sup>. Other differences would appear to relate to a division of labour among the satellite cells of the central nervous system. In myelinated peripheral nerve fibres, regardless of size, the internodal axon is invested with a myelin sheath and the nodal axon is supplied with specific processes by the same Schwann cell: the nodal processes are embedded in gap substance and the whole complex is surrounded by basement membrane<sup>4</sup>.

In the central nervous system, on the other hand, the internodal axon is invested with a myelin sheath by one or more glial processes<sup>12</sup> and the nodal axon is related to other glia or nerve processes<sup>10</sup>. The dual sheath-supporting and node-supporting roles of the Schwann cell would appear to be responsible for the specialized nature of the nodal and paranodal apparatus of peripheral nerve. The dichotomy of these roles in the central nervous system is associated with a simpler node-form: when glial processes are related to a central node they are irregular, are not embedded in gap substance and are not surrounded by a basement membrane<sup>13</sup>; no specific internal structure, no particularly intimate apposition to axonal membrane and no specific reception areas on the membrane have been seen. The relatively unspecialized nature of the central node and the occurrence of variants<sup>14</sup> make it very difficult to distinguish nodal axons from non-myelinated axons in transverse sections<sup>10</sup> and relative counts of mitochondria in nodal axon and nodal glia have not been possible. However, a reciprocal relationship between the numbers of internodal axonal mitochondria and the thickness of the myelin sheath was noted as fibres were traced back from the prelaminar region of the optic nerve. This was reflected in the histochemical activity of the mitochondrial enzymes, succinic and malic dehydrogenase, in the axons. Activity was highest in the non-myelinated prelaminar parts of the axons and fell off as they were traced back and

acquired myelin sheaths of increasing thickness. On the other hand, in the macroglia the response was predominantly oligodendrocytic, and thus post-laminar and associated with myelinated fibres. This suggestion that the citric acid cycle operates primarily within the axon of the non-myelinated part of the cat optic nerve, and within the satellite cells of the myelinated part, favours the concept of the oligodendrocyte as an energy-donor<sup>15</sup>, specifically at the central node. The response to histochemical tests for lactic dehydrogenase was also predominantly oligodendrocytic, suggesting that these cells have a capacity for anaerobic glycolysis: other evidence suggests that glia cells (mixed samples) may resort to this under conditions of intense nervous activity<sup>2</sup>. The response for  $\alpha$ -glycerophosphate dehydrogenase, on the other hand, was predominantly astrocytic, suggesting active lipid metabolism in these cells. It has been suggested that glia cells, which have a high lipid content (mixed samples), may resort to utilizing lipoproteins as an energy source<sup>13</sup>, but activity may well be concerned with phospholipid membrane production and turnover. These and other results, which will be reported in detail elsewhere, provide further evidence of the ultrastructural and enzymatic differentiation of satellite-cell types and of the complementary relationship between neurones and satellite cells. Histochemical investigations are being extended both in range of enzymes and sites for examination.

An understanding of the neurone-satellite cell relationship demands that all its vagaries be explored—perikaryal and axonal, central and peripheral. However, the interpretation of certain morphological differences revealed at different sites should be approached with caution. Despite their electron density, the polysaccharide-rich nodal gap substance and basement membrane of the peripheral node surely present no barrier to metabolites when particles as large as 150 Å can traverse the cornea<sup>16</sup>, with its chemically similar, but many times thicker, membranes: indeed, the matrix of the peripheral node may favour rather than hinder the movement of ions and facilitate

metabolic exchange at discrete intervals along the peripheral nerve fibre. From observations on the leech<sup>17,18</sup>, it would seem unlikely that satellite cells play an active part in the signalling activity of the nervous system or that they are directly concerned with the action potential mechanism of nerve cells. It is also unlikely that satellite-cell cytoplasm forms a significant part of the local electrotonic circuit which activates neighbouring nodes: gap substance and basement membrane are much more likely to be involved. Certainly, in the leech, the glia cell is not involved in the diffusion and probably not in the active transport of ions: the 150 Å intercellular spaces shown by electron microscopy serve as pathways for the flow of current and are utilized for the transport of ions and molecules as large as sucrose<sup>17,18</sup>. Progressive elimination of possible roles directs attention more than ever to the metabolic and myelinogenic aspects of the neurone-satellite cell relationship.

## SURVIVAL OF FROZEN CHONDROCYTES ISOLATED FROM CARTILAGE OF ADULT MAMMALS

By DR. AUDREY U. SMITH

National Institute for Medical Research, Mill Hill, London

FOR many years plastic surgeons have been successfully using autografts and homografts of fresh, living fibrocartilage in reconstructive surgery of the head, neck and chest in man<sup>1</sup>. Recently, living hyaline cartilage has been successfully homografted into joints of animals<sup>2-5</sup>. Similar techniques may be applicable in the treatment of human arthritis. One difficulty is to obtain fresh human cartilage when it is needed. The chondrocytes only survive for about one week when cartilage is stored *in vitro* at temperatures just above 0° C. Grafts of cartilage in which the cells are dead give less satisfactory results<sup>1</sup>. As long ago as 1957, Gibson<sup>6</sup> expressed the need for a method of banking fibrocartilage for long periods at low temperatures in a potentially viable state. A bank of hyaline cartilage may also soon be needed.

During the past 15 years various types of cells and tissues from adult mammals have been stored at low temperatures in a state of suspended animation in media containing glycerol<sup>7</sup>. So far, cartilage from adult mammals has not survived freezing in the presence of glycerol. For example, Curran and Gibson<sup>8</sup> found that the chondrocytes were killed after cooling cartilage to -15° C in saline containing 15 per cent glycerol. On the other hand, Heyner<sup>9,10</sup> found that cartilaginous bones from 17- and 18-day-old embryonic rats survived cooling to -79° C

in the presence of 15 per cent glycerol, provided that the matrix had previously been partially removed by tryptic digestion. Viability of the cartilage cells was assessed by elongation of the rudimentary bones in organ culture and by histological studies. Cartilage from older embryos or adult mammals does not survive similar treatment.

Recently, dimethyl sulphoxide (DMSO) has proved to be superior to glycerol in protecting certain adult mammalian cells and tissues, including human and bovine erythrocytes<sup>11</sup>, bone marrow<sup>12</sup>, the corneal endothelium<sup>13,14</sup> and smooth muscle<sup>15</sup> during freezing to, storage at, and thawing from, low temperatures. An essential feature of glycerol and DMSO is their low toxicity<sup>16</sup>. Their molecules must be in contact with and actually penetrate the living cells which are to be frozen and thawed; then, after thawing, they must be removed before the cells and tissues will resume their normal functions. DMSO diffuses into and out of cells and through capillary walls and tissue spaces more readily than does glycerol<sup>17</sup>. It has always proved more difficult to freeze tissues than to freeze isolated cells without loss of viability; tissues from adult mammals have a higher cell mortality than comparable embryonic tissues frozen, banked and thawed by the same technique. This may be due, in part, to the nature of the intercellular material which hinders equi-

bration of the component cells with protective substances in the medium both before cooling and during the process of separation of water as ice. The matrix of cartilage is composed predominantly of a mucopolysaccharide ground substance containing a variable proportion of collagen and elastic fibrils. If cartilage were to be kept alive during banking at low temperatures it would be essential to ensure the presence in and around the living chondrocytes of a protective agent such as DMSO. The concentration of this substance should not in itself be harmful, but it should be adequate to prevent damage due to electrolytes during the processes of freezing and thawing<sup>15</sup>.

An obvious way of attacking the problem was to start by liberating the chondrocytes from adult cartilage. Their viability before and after freezing in different media could then be assessed. Several methods have been described for isolating the cells from minute fragments of embryonic cartilage of birds and mammals by tryptic digestion<sup>18-20</sup>. Their ability to incorporate radioactive sulphur (<sup>35</sup>S) and to manufacture collagen and mucopolysaccharide in tissue cultures was tested. Hitherto, however, no method has been established for isolating chondrocytes in large numbers from pieces of fresh adult cartilage, although an ingenious technique for obtaining them in small numbers from fixed sections by microdissection has been described<sup>21</sup>. New methods had to be developed. My object was to remove the ground substance and fibrils in which the cells are embedded by successive treatment with different proteolytic enzymes at concentrations and under conditions which would not damage the cells.

The first enzyme selected was papain. When activated by cysteine, or any agent which reduces disulphide, papain removes mucopolysaccharides from cartilage and other tissues as shown by Thomas<sup>22</sup> and by Tsaltas<sup>23</sup>. The second enzyme was collagenase from *Cl. histolytica*, which digests native and denatured collagen and was purified and freeze-dried by MacLennan and his co-workers<sup>24,25</sup>. It was obtained from the Sigma Chemical Co., St. Louis, Mississippi. The third enzyme chosen was pronase (grade B), a protease obtained from *Streptomyces griseus* by Nomoto and his colleagues<sup>26</sup>, which was used to remove the zona pellucida of developing mouse eggs<sup>27,28</sup> and has also been used instead of trypsin to disperse mammalian cells in cultures<sup>29</sup>. Pronase was obtained from Calbiochem, Inc., Los Angeles.

The experimental method was as follows: rabbits, dogs and monkeys were the animals used. Strips of fibro-cartilage (2.0 × 0.4 × 0.1 cm) were cut from the pinna, and fragments of hyaline cartilage (less than 1 mm thick and less than 3 mm in length and width) were sliced from the articular surfaces of the larger joints. Human fibro-cartilage from a damaged meniscus from a knee joint, and hyaline cartilage removed at operation from an ankle joint were cut into similar-sized pieces. The strips of fibro-cartilage or 80-100 mg of hyaline cartilage were suspended in 4 ml. of Gey's balanced salt solution adjusted to pH between 7.0 and 7.4 by bubbling with air containing 5 per cent CO<sub>2</sub>. 0.4 ml. of a 1 per cent solution of crude papain was added to give a final concentration of 1 mg/ml. A solution of cysteine was added to give a final concentration of 0.003 M. After incubation for 1 h at +37° C the fragments of cartilage were washed. Some were fixed, embedded and sectioned histologically. They were stained with alcian blue and kernectrot and examined by ordinary illumination, or stained with euchrysin 3R and examined by fluorescence microscopy as previously described<sup>30</sup>. They did not show the staining reaction or the fluorescence characteristic of mucopolysaccharide ground substance. Other pieces of cartilage from animals and man were digested with papain, washed three times with 10 ml. of Gey's solution, and incubated with collagenase (0.2 mg/ml.) in Gey's solution at pH 6.8-7.4 for 16-20 h at +37° C. After this treatment blobs and strands of gelatinous material still remained. Under the phase contrast microscope the chondrocytes

could be clearly seen surrounded by amorphous material and delicate strands resembling elastic fibrils. A solution of pronase was then added to the medium containing collagenase, to give a final concentration of 0.2 mg pronase per ml. Incubation was continued for a further period of 16-24 h at +37° C. Sterile instruments, glassware and solutions, and aseptic techniques, were used throughout the enzyme treatment. Antibiotics were included in the media (penicillin 100 units per ml.; streptomycin 100 µg per ml., mycostatin 50 units per ml.). At the end of the 1.5-2 days' incubation the medium was turbid and contained minute visible particles but no fragments recognizable as cartilage. Prolonged digestion with trypsin (0.2 per cent) or any of the three enzymes used alone was less effective in disintegrating cartilage. The tubes were centrifuged, the supernatant fluid was discarded and the deposit resuspended in 10-15 ml. of Gey's solution. Centrifugation and re-suspension were repeated. After centrifuging for a third time the deposit was resuspended in 0.25 ml. of homologous serum or Gey's solution. Drops of the washed and concentrated suspension were mounted on slides coated with a thin film of 1 per cent agar in Ringer's solution. The preparations in serum were sealed and examined by phase contrast microscopy at +37° C. Those in Gey's solution were treated with an equal volume of euchrysin (1 in 50,000) and examined by fluorescence microscopy. Large numbers of intact isolated chondrocytes were seen. Those obtained from fibrocartilage contained one or more vacuoles and were often binucleate. Those from hyaline cartilage contained many granules and few if any vacuoles. When viewed by phase contrast microscopy at +37° C they took up amoeboid forms; when filmed by time-lapse cinematography they made active movements for periods varying from 6 h with chondrocytes from rabbit hyaline cartilage to 24 h with chondrocytes from the dog, monkey and man<sup>31</sup>. When stained with euchrysin and viewed by fluorescence microscopy their nuclei fluoresced a vivid yellowish green,

Fig. 1. Freshly isolated chondrocytes. a, From dog hyaline cartilage (× 1,500); b, from human hyaline cartilage, after treatment with 10 per cent DMSO (× 1,500)

Fig. 2. Chondrocytes after freezing to and thawing from  $-79^{\circ}\text{C}$ . *a*, From dog hyaline cartilage ( $\times 1,500$ ); *b*, from human hyaline cartilage ( $\times 1,250$ ).

the nuclear sex chromatin body fluoresced bright yellow in cells from female animals, while minute granules fluorescing a brilliant orange-red could be seen in the cytoplasm (see Fig. 1, *a* and *b*). The cytological details varied in the chondrocytes from fibro- and hyaline cartilage of the four species examined. Some naked nuclei and cellular debris could be seen both by phase contrast and by fluorescence microscopy. They were most numerous in the preparations of rabbit chondrocytes and comparatively rare in preparations of dog and human chondrocytes. In recent experiments on rabbit cartilage the concentrations of enzymes have been doubled. With the larger fragments of dog cartilage the concentration of papain has been increased to 4 mg/ml. and the concentrations of collagenase and pronase increased tenfold; the incubation period was reduced to 1.5 h with collagenase and 5 h with pronase. There were many isolated cells in suspension and no obvious increase in the numbers of dead cells, but some partially digested fragments remained.

The main object was to determine whether isolated chondrocytes would survive freezing and thawing. Washed deposits of the cells obtained from hyaline cartilage of the different species were suspended in 1-ml. volumes of medium containing 10 per cent v/v DMSO, 40 per cent rabbit serum and 50 per cent Gey's solution. The suspensions were sealed in ampoules and cooled slowly to  $-79^{\circ}\text{C}$  at the rate of approximately  $1^{\circ}\text{C}/\text{min}$  to  $-20^{\circ}\text{C}$  and  $4^{\circ}\text{C}/\text{min}$  between  $-20^{\circ}\text{C}$  and  $-79^{\circ}\text{C}$ . They were kept at  $-79^{\circ}\text{C}$  for periods varying from one hour to one week. The ampoules were then immersed in water at  $+40^{\circ}\text{C}$  to thaw their contents rapidly. The suspensions were diluted gradually with 1 ml. of serum and then with 8 ml. of Gey's solution to reduce the concentration of DMSO to 1 per cent. They were centrifuged and the deposit was resuspended in 0.25 ml. of serum or Gey's solution for examination by phase contrast microscopy or fluorescence microscopy.

A high proportion of the thawed chondrocytes from all four species were normal in appearance under the phase contrast and fluorescence microscopes (Fig. 2, *a* and *b*), but in each instance there were more naked nuclei and disintegrated cells than in preparations of unfrozen chondrocytes. In some cells the cytoplasmic granules were larger and more heavily stained than normal. Time-lapse cinematography showed that the intact frozen cells were highly active for 4–6 h at  $+37^{\circ}\text{C}$  (ref. 31). In preparations of frozen dog, monkey and human chondrocytes, active cells were present after 8 h and occasionally after 24 h at  $+37^{\circ}\text{C}$ . Comparatively few of the frozen rabbit chondrocytes survived for 8 h.

The viability of fresh and frozen rabbit chondrocytes was also tested by homografting on to cancellous bone in prepared defects either on the outer table of the iliac bone or on the head of the humerus. Six weeks later the grafted areas were removed at necropsy and processed histologically. The sections were stained with alcian blue and kernelectrot. They showed large numbers of apparently normal chondrocytes arranged in columns and surrounded by well-stained matrix, whether the isolated cells implanted had been frozen or not<sup>32</sup>.

The survival of homografts of fresh untreated cartilage is thought to be due to a protective effect of the mucopolysaccharides in the matrix<sup>33,34</sup>. The rapid re-formation of matrix may have been responsible for the absence of plasma cells and lymphocytes and other signs of a homograft reaction in the vicinity of our grafts of chondrocytes.

Methods are now being worked out for treating the articular surfaces of long bones of rabbit and dog with DMSO so as to preserve the viability of the chondrocytes during freezing, storage and thawing from low temperatures without disrupting the tissue.

I thank Dr. H. Rogers for advice, and Mr. P. J. Chesterman, Miss B. Bayley, Mr. M. Young and Mr. F. Wanless for their help.

## GROWTH OF CARCINOID TUMOURS IN TISSUE CULTURE

By DR. J. F. FOLEY and DR. RICHARD B. DAVIS\*

Department of Medicine and Eugene C. Eppley Institute for Research in Cancer and Allied Diseases, University of Nebraska College of Medicine, Omaha, and the Department of Medicine, University of Minnesota Medical School and University Hospitals, Minneapolis

IN recent years considerable knowledge has accumulated concerning the clinical course, pathology, and biochemistry of carcinoid tumours<sup>1</sup>. Much of this work has concerned the biochemical pathway of 5-hydroxytryptamine (5-HT) formation, and the effect of various 5-HT antagonists on this system. Examination of the metabolism of the tumour would be facilitated by its establishment in continuous tissue culture, free of *in vivo* variables. Moreover, as the embryonic origin of the argentaffin cell is disputed<sup>2</sup>, it would be of interest to observe the morphology of carcinoid cells *in vitro*. The results of our preliminary attempts to grow metabolically active carcinoid tumour cells in tissue culture are reported in this article.

Tumour tissue was obtained aseptically and placed immediately in balanced salt solution (BSS) (pH 7.2). The tissue was rinsed three times in BSS, minced into 1-mm cubes, and placed in collagenase (Worthington Biochemicals, 0.2 mg/ml. in BSS) for 5 h or 0.2 per cent trypsin (Difco 1:250 in BSS) for 40 min at 36.5° C. The specimen was shaken briskly for a short period to disperse the cells, and the supernate containing the cells was centrifuged at 60g and discarded. The cells were resuspended in growth medium and counted with a haemocytometer, and appropriate numbers of cells were plated in 60 × 15 mm Petri dishes (Falcon Plastic Co.). All cultures were incubated at 36.5° ± 0.3° C in a humidified continuously changed atmosphere of 2.5 per cent carbon dioxide in air. Growth media consisted of: (A) 70 per cent basal growth medium 199 (ref. 3) + 15 per cent foetal calf serum (Hyland Laboratories) and 15 per cent human cord serum (Microbiological Associates); (B) 80 per cent basal growth medium 199 + 10 per cent foetal calf and 10 per cent adult human serum (type O or A Rh-positive, from a local blood bank); (C) 80 per cent Eagle's medium<sup>4</sup> minus phenol red and 10 per cent foetal calf and 10 per cent adult human serum. Penicillin (0.1 mg/ml.), streptomycin sulphate (0.1 mg/ml.) and mycostatin (0.05 mg/ml.) were added to growth media.

The supernatant fluid obtained after removal of particulate matter by centrifugation at 2,000g for 10 min was extracted after protein precipitation and assayed for 5-HT by fluorimetry<sup>5</sup>. Cell suspensions in BSS were diluted 1:5 with distilled water, frozen and thawed three times, and then assayed for 5-HT. After protein precipitation of fluid and lysed cells with 50 per cent re-distilled trichloroacetic acid and chromatography on 'Decalco' resin<sup>6</sup>, histamine was determined by fluorimetry<sup>7</sup>. 5-Hydroxyindoleacetic acid (5-HIAA) was determined by fluorimetry after protein precipitation<sup>8</sup>. The first cell line was obtained at autopsy from a portal lymph node almost totally replaced by carcinoid tumour. The cellular morphology initially resembled that of a fibroblastic-like cell (Fig. 1). The majority of the cells were large and oblong to rounded in shape. At the time of the fourth sub-culture, a portion of cells were added to growth medium B. During the first two sub-cultures in medium B, the cells decreased in number and became very granular and large (Fig. 2), similar to cells in hormonally active human hydatid moles<sup>9</sup>. The cells then reverted to a fibroblastic-like appearance.

The Masson-Fontana stain<sup>9</sup> for argentaffin granules with appropriate controls was negative on sub-cultures 2 and 6. Secretion of 5-HT into growth medium was not found in the primary or third sub-culture, but a five-fold increase in supernatant 5-HT was seen in the medium from cells in sub-culture 4 in growth medium B versus no increase in the medium from cells of the same sub-culture incubated in growth medium A (Table 1).

Fig. 2. Carcinoid cells of line 1 in sub-culture 5 in medium B. Note marked granularity of cells. (Unstained; × 152)

\* Holder of a Research Career Program award (5-K3-HE 14919-03) of the National Heart Institute, U.S. Public Health Service.

Table 1. HORMONAL ACTIVITY OF CARCINOID CELL LINE 1

Medium	Sub-culture	5-HT concentrations ( $\mu\text{g/ml.}$ or per $10^6$ cells)				Cells
		Control*	from cells	Medium containing 5-HTP	Medium containing 5-HTP	
A	Primary	0.32	0.09	—	—	—
A	2	—	—	—	—	0.00
A	3	0.58	0.21	0.27	—	—
A	4	0.41	0.24	—	—	—
B	4	0.18	1.00	—	—	—
B	5	—	—	—	—	8.2
B	6	0.11	0.07	0.12	0.11	0.07
B	7	0.20	0.02	0.10	—	—

All media were placed on cell cultures 48 h prior to assay, except for passage six, which was 72 h, and passage seven, which was 96 h.

\* Indicated medium incubated at  $37^\circ\text{C}$  without cells.

Growth media containing graded amounts of 5-hydroxytryptophan (5-HTP) were incubated with cultures containing 50,000 cells in the sixth sub-culture for 72 h, without enhancing 5-HT production (Table 1). Cells from the second sub-culture contained no 5-HT whereas substantial amounts were found in the fifth sub-culture (Table 1). Histamine has been found previously in carcinoid tumour tissue<sup>10</sup>, and assay of cell lysates demonstrated 8.3 and 20  $\mu\text{g}$  of histamine per million cells in sub-cultures 2 and 5 in medium A and B respectively. No histamine was found in the growth medium from cells in sub-culture 5 in medium B, and histamine was absent in control fibroblastic-like cells from foetal human skin and intestine and from a human benign breast lesion.

Lymph nodes partially replaced by carcinoid tumour were obtained at the time of the laparotomy from a second case of the carcinoid syndrome. The cells readily established in culture were typically fibroblastic-like in appearance. Growth medium incubated with the cells from sub-culture 2 showed no increase in 5-HT or histamine over that of the control fluid concentrations. An argentaffin stain on cells of the first sub-culture was negative. Although morphologically similar to the other cell lines, these cells may well have been derived from connective tissue associated with the tumour.

Tumour nodules obtained at autopsy from the liver of a third patient were the source of the third cell line. Complete monolayers of cells morphologically similar to fibroblastic-like cells grew out in 11 days. Although morphologically similar to those from the other two

Fig. 3. Carcinoid cells of line 3 in sub-culture 3. Note argentaffin-positive granules. (Masson-Fontana stain,  $\times 1,120$ )

biopsies, typical argentaffin-positive granules were present in sub-cultures 1 and 3 (Fig. 3). Fluid used to grow the cells in sub-cultures 1 and 2 did not contain increased amounts of 5-HT or 5-HIAA (Table 2), but cells from sub-cultures 2 and 3 contained appreciable amounts of 5-HT (Table 2). Control fibroblastic-like cells from foetal human intestine, lung and skin in sub-culture 2 and from a human benign breast biopsy in sub-culture 2 contained no measurable 5-HT. Fluids from these fibroblastic-like cultures had no increase in 5-HT content over control fluids.

Table 2. HORMONAL ACTIVITY OF CARCINOID CELL LINE 3

Medium	Sub-culture	5-HT concentration ( $\mu\text{g/ml.}$ or per $10^6$ cells)		5-HIAA concentration ( $\mu\text{g/ml.}$ )	
		Control*	from cells	Control*	from cells
B	Primary	0.27	0.06	—	—
C	1	0.31	0.28	1.9	0.16
C	2	0.31	0.09	8.6	0.16
C	3	—	—	2.8	0.09

Media from primary culture placed on cell cultures 48 h prior to assay; those from sub-cultures 1 and 2, 72 h.

\* Indicated medium incubated at  $37^\circ\text{C}$  without cells.

The presence of 5-HT in cell lines 1 and 3, and of argentaffin-positive granules in 3, strongly suggests that these originated from carcinoid cells. Since it is known that argentaffin-positive granules may not be found in hormonally active tumours, it was not unexpected to find that the first cell line contained no such granules. Increased 5-HT was noted only once in the fluids used to grow the three carcinoid cell lines, despite addition of 5-hydroxytryptophan to the medium. Thus the factors leading to 5-HT secretion or release *in vitro* remain as obscure as the hormonal or environmental factors *in vivo*, although it is recognized that epinephrine administration can precipitate increases of plasma 5-HT in patients with carcinoid tumours<sup>11</sup>.

The 5-HT and histamine contents of the cells were considerably higher than those found in a murine mast cell in continuous culture by Day and Green<sup>12</sup>. Of interest in their investigations was the variable 5-HT and histamine activity *in vitro*, both qualitatively and temporally, over a two-year period. Our limited results indicated a similar variability in activity. The dissimilarity in *in vitro* behaviour among the cell lines correlates with known *in vivo* activity of carcinoid tumours, which are recognized to vary greatly in their metabolic activity and clinical manifestations<sup>1</sup>. Although the origin of argentaffin cells is disputed<sup>2</sup>, carcinoid tumours in the broad sense have been classified as being fore-, mid- and hind-gut in origin, favouring an entodermal origin<sup>13</sup>. Each of the carcinoid cell lines grown *in vitro* was derived from metastasis from a small bowel primary tumour. The cells were fibroblastic in appearance, suggesting that they were derived from mesenchyme.

## ASTROPHYSICS

Possible Magnetospheric Phenomena  
associated with Neutron Stars

WITH the discovery of X-ray sources in the sky<sup>1,2</sup>, speculation has arisen that they might be associated with neutron or hyperon stars formed during the internal collapse which triggers off supernova explosions (probably of type I). Rates of cooling of neutron star models have been calculated by Morton<sup>3</sup>, Chiu and Salpeter<sup>4,5</sup>, and Tsuruta<sup>6</sup>. It appears (J. Bahcall, personal communication) that the importance of the early cooling by emission of neutrinos from the 'Urca' process has been underestimated in the foregoing investigations. With rough allowance for this effect, the calculations of Miss Tsuruta indicate that a neutron star will rapidly cool to  $3$  or  $4 \times 10^8$  °K, but that after  $10^5$  years its surface temperature will still be about  $2 \times 10^8$  °K.

During the earlier part of 1964 evidence unfavourable to the neutron star hypothesis for X-ray sources accumulated. Thus Bowyer, Byram, Chubb and Friedman<sup>7</sup> showed from a lunar occultation measurement that the diameter of the X-ray source associated with the Crab Nebula is about one light year, and there appeared to be a deficiency of soft X-rays from it. At the symposium on "Neutron Stars and Celestial X-ray Sources", held at the Goddard Institute for Space Studies during March 1964, Giacconi and Friedman both reported crude spectral estimates which suggested that the strongest X-ray source, in Scorpius, if thermal, would have a temperature of about  $1$  or  $2 \times 10^7$  °K—much too hot to be interpreted as a neutron star.

Many more measurements were reported at the second Texas Conference on Relativistic Astrophysics in December 1964. Friedman, for example, reported that the soft X-ray flux from both the Crab Nebula and the Scorpius source has been greatly underestimated; his newer determination of the equivalent thermal temperature of the Scorpius source was  $2 \times 10^6$  °K. He also reported that ten X-ray sources had now been identified and that these formed a distribution flattened toward the galactic plane. Also at the December 1964 Texas Conference Giacconi reported that the angular diameter of the Scorpius source is less than  $8$  min of arc. However, Clark, at the same Conference, reported that the Crab Nebula emitted a significant flux of  $\sim 30$  keV X-rays, consistent with the synchrotron emission picture of Woltjer<sup>8</sup>. Fisher, again at the second Texas Conference, reported that the X-ray energy spectrum from the Scorpius source contained too large a flux of higher energy X-rays to be consistent with a pure thermal spectrum of  $2 \times 10^6$  °K.

It is the purpose of the present communication to suggest that the discrete X-ray sources may be neutron stars with an associated magnetosphere. The X-ray spectrum would thus consist of a thermal component emitted from the photosphere and a non-thermal synchrotron component emitted by trapped electrons accelerated in the magnetosphere.

Magnetic fields are commonly associated with stars. Woltjer<sup>8</sup> has pointed out that neutron stars may contain magnetic fields with strengths up to  $\sim 10^{14}$  gauss, which would be formed during the compression of matter which forms the neutron star. This compression occurs during the hydrodynamic collapse of a pre-supernova star. Colgate and White<sup>9</sup> have found that a degenerate neutron core starts to build up in such a collapse, and additional matter descending on this core releases large amounts of gravitational potential energy. The deposition of this energy forms a strong shock wave which ejects the outer layers of the star. We must expect that the internal magnetic lines of force would be drawn radially outward

in this explosion. However, the rotation of the remaining neutron star would twist the lines of force in the inner region so that they would have to reconnect to form a self-contained magnetosphere.

The surface temperature of a neutron star is comparable with the kinetic temperature in the solar corona, but its radius is orders of magnitude less than that of the Sun. Hence the stellar wind associated with a neutron star will be negligibly small compared with the solar wind, according to the hydrodynamic model for coronal expansion<sup>10</sup>, unless much higher kinetic temperatures are produced in a corona around the neutron star. It should not be ruled out that the mechanism to be discussed here might produce these higher kinetic temperatures, in which case there could also be a bremsstrahlung component in the X-ray emission. The heating of the solar corona appears to be produced by generation of acoustic, gravity and hydromagnetic waves by turbulence in the convective layers below the solar photosphere. It is clear that no similar convective region can exist in a neutron star<sup>6</sup>.

However, the neutron star is capable of storing gravitational potential energy in the form of radial oscillations. Such oscillations will have a period in the millisecond range (F. J. Dyson, personal communication). The shock wave which ejects matter in the supernova explosion will eject only the outer layers; the inner layers will be accelerated outward by the shock but will fall back on to the neutron star. It seems likely that a substantial amount of energy may thus be stored in the resulting radial oscillations. The gravitational binding energy of a neutron star is a sensitive function of the mass<sup>6</sup>, but it may typically amount to several per cent of the rest mass energy. Hence it may be possible to store  $\sim 10^{52}$  ergs as vibrational energy in such a star. This is 5 or 6 orders of magnitude greater than the thermal energy content of a neutron star at the end of the initial rapid neutrino cooling stage<sup>6</sup>.

The radial oscillations will generate hydromagnetic waves at parts of the magnetic field which emerge from the photosphere at some angle to the normal. These waves will traverse the magnetosphere and can accelerate electrons. If this picture holds for the Crab Nebula, then evidently the electrons escape from the magnetosphere into the radial magnetic field system of the surrounding expanding envelope. The electrons will initially emit X-rays by the synchrotron process, but their synchrotron lifetime for X-ray emission is only about one year<sup>8</sup>. This would account for the observation that the region of X-ray emission in the Crab Nebula is smaller than the region of optical synchrotron emission.

If these considerations are correct, it is evident that many other non-thermal phenomena will be associated with the mechanical energy of vibration of neutron stars, and hence that extensive theoretical investigations of such phenomena may be rewarding.

## PHYSICS

## Release of Gravitational Energy in General Relativity

THE clarity of Prof. McCrea's<sup>1</sup> recent treatment of the Schwarzschild singularity and of his discussion on the release of gravitational energy in general relativity opens up the possibility of a slightly different point of view. The present contribution may be of some academic and pedagogic interest.

It is assumed, following McCrea, that a free particle of rest mass  $m$  is projected inwards from infinity towards a spherical body of mass  $M$  and radius  $R$ . The free particle strikes the surface of the mass  $M$  and a fraction of its energy is released and then radiated away as a single particle (either a photon or a neutrino) of zero rest mass.

Failing a rational theory of the two-body problem we are compelled to use the Schwarzschild exterior metric for  $M$ , and to assume that the mass  $m$  is infinitesimally small in comparison with  $M$ . In many practical applications this procedure is justified. But if  $M$  approaches its limiting critical radius it is doubtful whether in the limit the neglect of the effect of the infinitesimal mass  $m$  is always possible. The following treatment takes into account the effect of  $m$  in an approximate way.

The Schwarzschild exterior metric is:

$$ds^2 = (1 - 2M/r)dt^2 - (1 - 2M/r)^{-1}dr^2 - r^2(d\theta^2 + \sin^2\theta d\phi^2)$$

with  $c = G = 1$ . Consider a free particle of infinitesimal rest mass  $m$  having an energy at infinity of:

$$E_m(\infty) = \alpha m, \alpha \geq 1 \quad (1)$$

and moving in the direction of the central mass  $M$ . Relative to an observer on the surface of  $M$  the free particle arrives with an energy of:

$$E_m(R) = E_m(\infty) (1 - 2M/R)^{-\frac{1}{2}} \quad (2)$$

After striking the surface, the energy in excess of some amount, say  $\beta m$ , is converted into a particle of zero rest mass of energy:

$$E_0(R) = E_m(R) - \beta m \quad (3)$$

In general,  $\beta \geq 1$ . When the constituent particles of  $M$  are stationary the free particle can come to complete rest, and in this event  $\beta = 1$ . Otherwise,  $\beta > 1$  on the average, where  $\beta m$  is the mean energy of the constituent particles at the boundary. The radiated particle of zero rest mass now moves outwards to infinity following a null-geodesic and ultimately has an energy of:

$$E_0(\infty) = E_0(R) (1 - M'/R)^{\frac{1}{2}} \quad (4)$$

Combining equations (1), (2), (3) and (4), it follows:

$$E_0(\infty) = E_m(\infty) \left\{ (1 - 2M/R)^{-\frac{1}{2}} - \beta/\alpha \right\} (1 - 2M'/R)^{\frac{1}{2}} \quad (5)$$

The argument so far is identical with McCrea's with the exception of the modification in equation (4), where  $M'$  is used instead of  $M$ . Let us suppose for the moment that  $M = M'$ . Furthermore, let us suppose that in principle it is possible for  $2M \rightarrow R$ ; then in the limit, it follows from equation (5) that:

$$E_0(\infty) = E_m(\infty) \quad (6)$$

This means, when the mass  $M$  has the critical value, the whole energy of the free particle is converted into radiation.

But in actual fact the free particle falls towards a mass of  $M$ , and the radiated particle escapes to infinity from a mass of  $M' = M + \beta m$ . So long as  $2M' \ll R$ , the infinitesimal increase in  $M$  is of no importance. However, when  $2M' \rightarrow R$ , in the limit it follows:

$$E_0(\infty) = 0 \quad (7)$$

and this result holds no matter how small  $\beta m$  is made. It is seen that the addition of the infinitesimal contribution to the central mass is of considerable importance when the central mass is close to its critical value.

If the mean density of  $M$  obeys an equation of the form:

$$\rho = \text{constant} \times M^\mu \quad (8)$$

then equation (5) can be rewritten as:

$$E_0(\infty) = E_m(\infty) \left[ \left\{ 1 - \left( \frac{M}{M_c} \right)^\nu \right\}^{-\frac{1}{2}} - \frac{\beta}{\alpha} \right] \left\{ 1 - \left( \frac{M + \beta m}{M_c} \right)^\nu \right\}^{\frac{1}{2}} \quad (9)$$

where  $M_c$  is the limiting Schwarzschild mass and:

$$\nu = \frac{2 + \mu}{3} \quad (10)$$

When  $\mu = -2$ , equation (9) does not apply, since the ratio  $2M/R$  remains constant. For  $\mu \leq -2$ , the mass  $M$  can be increased indefinitely and the Schwarzschild singularity is never attained. However, this represents an unrealistic relation between mean density and mass, and in fact only positive values of  $\mu$  should be considered.

Imagine that the mass  $M$  is built up, step by step, by releasing in succession  $n$  free particles of initial energy  $\alpha m$ , each of which contributes  $\beta m$ . Hence,  $M = n\beta m$ , after the  $n$ th particle has arrived. Also let  $M_c = N\beta m$ , where  $N$  is the maximum possible number of contributions. For the  $n$ th particle, equation (9) is:

$$E_0(\infty) = E_m(\infty) \left[ \left\{ 1 - \left( \frac{n-1}{N} \right)^\nu \right\}^{-\frac{1}{2}} - \frac{\beta}{\alpha} \right] \left\{ 1 - \left( \frac{n}{N} \right)^\nu \right\}^{\frac{1}{2}} \quad (11)$$

Consider now the final stages of the building-up process, in which  $n = N - \Delta N$ , and  $\Delta N$  is a positive integer small compared with  $N$ . That is,  $\Delta N = \dots 3, 2, 1, 0$ . Equation (11) is now, for  $\nu > 0$ :

$$E_0(\infty) = E_m(\infty) \left\{ \left( \frac{\Delta N}{\Delta N + 1} \right)^{\frac{1}{2}} - \frac{\beta}{\alpha} \left( \frac{\Delta N}{N} \right)^{\frac{1}{2}} \right\} \quad (12)$$

For infinitesimally small increments of mass,  $1/N \rightarrow 0$ ; and therefore this equation is approximately:

$$E_0(\infty) = E_m(\infty) \left( \frac{\Delta N}{\Delta N + 1} \right)^{\frac{1}{2}} \quad (13)$$

Thus, the efficiency of converting matter into radiation is... 87 per cent, 82 per cent, 71 per cent, 0, for  $\Delta N = \dots 3, 2, 1, 0$ . When the last free particle is added (that is,  $\Delta N = 0$ ), the mass becomes critical and the conversion ratio  $E_0(\infty)/E_m(\infty)$  drops to zero because the final radiated particle is unable to escape in a finite time. On differentiating equation (12) it is found that the conversion ratio has a maximum value of:

$$E_0(\infty)/E_m(\infty) = 1 - \frac{3}{2} \left( \frac{\beta^2 \nu}{\alpha^2 N} \right)^{\frac{1}{2}} \quad (14)$$

and occurs at:

$$n = N - \left( \frac{\alpha^2 N}{\beta^2 \nu} \right)^{\frac{1}{2}} \quad (15)$$

If a critical mass equal to a solar mass is built up from free particles of nucleonic mass, and if  $\alpha$ ,  $\beta$ , and  $\nu$  are approximately unity, then the conversion ratio has a maximum value of  $1 - 10^{-19}$ , which occurs at  $\Delta N \sim 10^{19}$  when the mass is  $10^{-5}$  g short of its critical value.

The model outlined here is interesting from the point of view of the conservation of energy principle. If, for example, the initial energy is expressed as the sum of two terms:

$$E_m(\infty) = E_0(\infty) + \beta m (1 - 2M/R)^{\frac{1}{2}}$$

where the first term on the right-hand side is the final radiation energy and the second term is the energy lost

to  $M$ , it follows from equation (5) that  $M = M'$ , and therefore  $\beta$  must be equal to zero. Evidently, the above equation does not provide a proper energy balance and omits a term for the binding energy. The original free particle divides on impact with  $M$  into two particles, and on separating these two particles exert a gravitational effect on each other. Conservation of energy therefore requires that:

$$E_m(\infty) = E_0(\infty) + \beta m(1 - 2M/R)^{\frac{1}{2}} + \Delta E \quad (16)$$

where  $\Delta E$  is the binding energy of the two particles. By comparing (5) and (16) it follows that:

$$\begin{aligned} \Delta E &= E_m(\infty) \left\{ (1 - 2M/R)^{-\frac{1}{2}} - \beta/\alpha \right\} \left\{ (1 - 2M/R)^{\frac{1}{2}} - (1 - 2M'/R)^{\frac{1}{2}} \right\} \\ &= E_m(\infty) \left\{ 1 - \frac{\beta}{\alpha} \left( \frac{\Delta N + 1}{N} \right)^{\frac{1}{2}} \right\} \left\{ 1 - \left( \frac{\Delta N}{\Delta N + 1} \right)^{\frac{1}{2}} \right\} \quad (17) \end{aligned}$$

For  $\Delta N \gg 1$ , it is seen that  $\Delta E$  is negligibly small. However, the binding energy is no longer negligible when  $\Delta N$  becomes small, and for  $\Delta N = 0$  one has  $\Delta E = E_m(\infty)$ . The dependence of the binding energy on  $M$  is an example of the non-linear superposition of gravitational fields.

In a gravitational field the rest mass of a particle is modified. Thus, at the surface of  $M$  it is:

$$m(R) = m(1 - 2M/R)^{\frac{1}{2}} \quad (18)$$

where  $m$  is the rest mass at infinity. It has been conjectured<sup>1</sup> that an infinite number of free particles must be added before  $M$  attains its critical value. It is argued that as  $2M \rightarrow R$  each free particle makes a vanishingly small contribution of  $m(R)$  to  $M$ , and therefore an infinite number of particles must be used in the process. Neither McCrea's results nor the present results support this conclusion. The rest mass  $m$ , as observed at infinity, is an invariant proper mass for all local observers. The mass  $m(R)$  is the rest mass at  $R$  as deduced by an observer at infinity, and it is not the rest mass for an observer at  $R$ . The contribution made to  $M$ , as deduced by a local observer, is the proper mass  $m$ . Hence, only a finite number of particles are necessary for  $M$  to reach its critical value.

### Uniqueness of the Mass-surface Relative to Iron-56

In practice, the mass of a neutral atom is expressed in terms of a particular nuclidic mass which is assumed to have an integral value and is termed the primary standard. With  $^{12}\text{C}$  as the primary standard ( $^{12}_6\text{M} = 12u$ ) nuclidic masses are found to be close to integral values and the difference between the measured mass ( $^{A}_Z\text{M}$ ) and the integral value  $Au$  is called the 'mass excess'<sup>1</sup>. Alternatively, the mass of a nuclide ( $A, Z$ ) relative to  $^{12}\text{C}$  could be expressed in the form:

$$^{A}_Z\text{M} = [A + z(\Delta)^{A}_{12}] u \quad (1)$$

where  $z(\Delta)^{A}_{12}$  is a small proper fraction ( $\pm$ ) which will be referred to as the 'mass fraction'. It should be noted that the 'mass fraction' is a dimensionless quantity whereas the 'mass excess' equals  $z(\Delta)^{A}_{12} u$ .

It is evident from a comparison<sup>2</sup> of recent nuclidic masses (relative to  $^{12}\text{C}$ ) with earlier values (relative to  $^{16}\text{O}$ ) that certain characteristics of the mass surface  $z(\Delta)^A = \Phi(A, Z)$  are dependent on the choice of primary

standard. In particular,  $^{90}\text{Zr}$  has the least value of  $(\Delta)_{16}$  whereas  $^{118}\text{Sn}$  has the least value of  $(\Delta)_{12}$ ; in other words, the location ( $A, Z$ ) of the minimum of the mass surface is dependent on the choice of primary standard. This suggests that it might be possible to choose the primary standard so that it corresponds to the minimum of the mass surface; such a primary standard would render all mass excesses positive. It is therefore of interest to examine the nature of the dependence of the mass fraction on the choice of primary standard and thereby establish a criterion for the nuclide that would have the least mass fraction when employed as the primary standard.

Let us consider changing to a new scale where the new unit of mass equals  $(1 + \phi)u$ , then the mass of the nuclide ( $A, Z$ ) on the new scale is given by the equation:

$$^{A}_Z\text{M} = [A + z(\Delta)^{A}_{12}]/(1 + \phi) \text{ new mass units} \quad (2a)$$

Assuming that the change of unit does not alter the 'mass number' we can write:

$$^{A}_Z\text{M} = [A + z(\Delta)^{A}_n] \text{ new mass units} \quad (2b)$$

where  $z(\Delta)^{A}_n$  is the new mass fraction. A comparison of equations (2a) and (2b) yields:

$$z(\Delta)^{A}_n = [z(\Delta)^{A}_{12} - \phi A]/(1 + \phi) \quad (3)$$

The convention of assigning an integral mass to the primary standard requires that  $z(\Delta)^{A}_n$  for the new standard be equal to zero. Thus equation (3) shows that  $\phi$  equals the value of  $z(\Delta)^{A}_{12}/A$  for the nuclide that is chosen as the new standard. The quantity  $z(\Delta)^{A}_{12}/A$  is the equivalent of Aston's so-called 'packing fraction' and will be represented by the symbol  $zf^{A}_{12}$ . Accordingly, possible values of  $\phi$  are given by the packing-fraction surface ( $zf^{A}_{12}$  versus  $A$  and  $Z$ ).

The dependence of the packing-fraction surface on the choice of primary standard is given by the equation:

$$zf^{A}_n = (zf^{A}_{12} - \phi)/(1 + \phi) \quad (4)$$

which is obtained by dividing equation (3) by  $A$ . A consideration of primary standards by Mattauch<sup>3</sup> includes an approximate form of equation (4). Equation (4) shows that, with a change in the primary standard, each packing fraction is changed by the same amount, except for the scale factor  $(1 + \phi)$ ; the effect can be regarded as a displacement of the packing-fraction surface parallel to the  $f$  axis.

It is well known that the packing-fraction surface has a minimum; we designate the nuclide with the least value of  $zf^{A}_{12}$  as  $(A_m, Z_m)$  and note that the same nuclide would have the least value of  $zf^{A}_n$ . It follows that if the nuclide  $(A_m, Z_m)$  were taken as the primary standard, its packing fraction would be zero and all other values of  $zf^{A}_n$  would be positive. Consequently all mass fractions relative to  $(A_m, Z_m)$  would be positive and the nuclide  $(A_m, Z_m)$  would have the least mass fraction, which would be zero. Therefore the nuclide  $(A_m, Z_m)$  constitutes the required primary standard.

Empirically it is found that for  $A$  equal to a constant, the most-stable isobar has the smallest mass fraction and therefore the smallest packing fraction. Thus, to identify the nuclide  $(A_m, Z_m)$ , it is sufficient to consider packing-fractions for most-stable isobars. The minimum of the packing-fraction surface is in the region  $50 < A < 70$ ; the packing fractions, and their errors, for nuclides with the least mass excess for each mass number from 50 to 68 are given in Table 1. Examination of the values reveals that the packing fraction for the nuclide  $^{56}\text{Fe}$  is uniquely the smallest in the group and consequently is the least value of  $zf^{A}_{12}$  for all values of  $A$  and  $Z$ . Accordingly the nuclide  $(A_m, Z_m)$  is identified as  $^{56}\text{Fe}$ .

The use of the nuclide  $^{56}\text{Fe}$  as the primary standard would retain the conventional mass numbers; the condition

\* Values from Everling, König, Mattauch and Wapstra<sup>2</sup>.

assumed for equation (2b) would therefore be satisfied. Furthermore, <sup>56</sup>Fe is the only 'primary standard' nuclide that would render all mass excesses positive; in this respect it would therefore constitute a unique primary standard.

Recalling that  $\phi$  equals the value of  $z f^{A}_{12}$  for the nuclide that is chosen as the new primary standard, it follows that if <sup>56</sup>Fe were the primary standard,  $\phi$  would have the least possible value; likewise, the new unit of atomic mass  $(1 + \phi)u$  would have the least possible value. Furthermore, it is apparent from equation (3) that each mass fraction relative to <sup>56</sup>Fe would have the greatest possible value. Accordingly, the mass of a nuclide ( $A, Z$ ) relative to <sup>56</sup>Fe could be expressed in the significant form:

$$\frac{A}{Z}M = [A + z(\Delta)A_{\max}] U_{\min} \quad (5)$$

Thus the mass surface  $z(\Delta)A_{\max} = \Phi(A, Z)$  is unique not only because all the values are positive but also because each value is a maximum.

Although the mass excess depends on the primary standard, the difference (in MeV) between the mass excesses for two isobars is independent of the primary standard. Thus in the investigation of isobaric transitions, for example,  $\beta$ -decay, a mass-excess diagram ( $\Delta$  versus  $Z$ ) serves as an energy diagram. On the other hand, when there is a

change in the mass number, for example,  $\alpha$ -decay, the difference (in MeV) between two mass excesses is dependent on the primary standard. However, the difference between two mass excesses relative to <sup>56</sup>Fe is a maximum and therefore corresponds to a unique energy difference. This suggests that the mass surface relative to <sup>56</sup>Fe would be appropriate for the investigation of the energetics of nuclidic transformations in general. In this regard, it is of interest to note that the mass excess relative to <sup>56</sup>Fe is potentially the largest portion of the nuclidic mass that can be transformed into energy. Thus the mass surface relative to <sup>56</sup>Fe has a special significance and as a potential-energy surface is unique, inasmuch as the lowest point on the surface corresponds to zero potential energy.

Conversion from the <sup>12</sup>C scale to the <sup>56</sup>Fe scale<sup>1</sup> is given by the relation:

$$\frac{A}{Z}M = [A + z(\Delta)A_{12}]/(1 + z f^{56}_{12}) U_{\min} \quad (6)$$

Thus, using the heaviest stable nuclide (<sup>209</sup>Bi) as an example:

$$\begin{aligned} \frac{209}{83}M &= (209 - 0.01958)/(1 - 0.0011619) U_{\min} \\ &= (208.98042)/(0.9988381) U_{\min} \\ &= 209.22352 U_{\min} \end{aligned} \quad (7)$$

A graphical representation of mass fractions, relative to <sup>56</sup>Fe, for most stable isobars is given in Fig. 1. For odd values of  $A$  they are shown as energy-levels whereas for even values of  $A$  they depict what might be termed a mass-fraction curve; the latter is a profile of the mass surface. It is noteworthy that all nuclidic masses relative to <sup>56</sup>Fe are given directly in terms of the mass number  $A$  and the mass fraction  $z(\Delta)A_{\max}$ .

I thank Prof. P. A. Fraser for his advice, and Dr. J. F. Hart for the use of the facilities of the Computer Centre.

## Chlorine-38 and Sulphur-38 produced by Cosmic Radiation

DURING the past few years several cosmic-ray spallation products of atmospheric argon have been found in rain water and aerosols. The first observed argon spallation product was <sup>32</sup>P (ref. 1), and was reported to be present in rain water in 1955. During the next two years the presence of <sup>36</sup>Cl (ref. 2), <sup>35</sup>S (ref. 3), <sup>33</sup>P (ref. 4) and <sup>22</sup>Na (ref. 5) were reported. In December of 1963 an additional radionuclide, <sup>24</sup>Na (ref. 6), was reported to be present in rain water. The radionuclides <sup>38</sup>Cl and <sup>38</sup>S have now been detected in rain water for the first time.

Our interest in radionuclides produced by cosmic rays in the atmosphere is concerned with the fall-out rates and mechanisms involved in the deposition of air-borne radionuclides. The ratio of those cosmic-ray produced radionuclides in rain water which have half-lives of the order of that required for a rain cloud to form should provide valuable information about both cloud formation and the washing of the atmosphere by rain.

Estimates of the expected production-rates of the possible spallation products of argon using both the methods of Rudstam<sup>7</sup> and of Baranovskii and Murin<sup>8</sup> showed that <sup>38</sup>Cl (half-life, 37.3 min) should be present in the atmosphere at concentrations comparable with <sup>36</sup>Cl. The calculations also indicated that <sup>38</sup>S (half-life, 2.9 h) should be present at a concentration of about an order of magnitude lower.

The decay schemes of these radionuclides permit direct measurement of their concentrations by coincidence-

\*  $\pm$  values are the S.D. for the measurements.

† Not measured.

counting techniques. The decay of  $^{38}\text{Cl}$  involves emission of a 1.60- and a 2.16-MeV  $\gamma$ -ray in cascade. The radionuclide  $^{35}\text{S}$  decays to  $^{36}\text{Cl}$  and the cascade of  $^{36}\text{Cl}$  can therefore be used in its measurement. The decay of the radionuclide  $^{36}\text{Cl}$  involves emission of 0.246- and 1.226-MeV photon cascades, and coincidence techniques are also applicable to its measurement.

All the measurements considered here were made using a  $\gamma$ -ray spectrometer of the type described by R. W. Perkins<sup>9</sup>. The sample was placed between the two anti-coincidence shielded NaI(Tl) detectors (4 in. thick  $\times$  6 in. diam.) which fed their respective signals to two analogue to digital converters of a 4096 channel multiparameter analyser. Total absorption events which occurred simultaneously in the two crystals were stored in the energy-energy plane of the memory at a point unique to these two energies. A thin lead absorber, covering the area between the crystals not occupied by the sample, eliminated backscatter interference at the  $^{36}\text{Cl}$  coincidence energy from the naturally occurring  $^{208}\text{Tl}$  in air samples.

The counting efficiencies (counts per disintegration) for  $^{36}\text{Cl}$  and  $^{38}\text{Cl}$  were only 0.010 and 0.067 respectively; however, the background counting-rates are extremely low, 0.008 c.p.m. and 0.12 c.p.m., respectively. Also, the Compton interference at the  $^{36}\text{Cl}$  coincidence peak is negligible and at the  $^{38}\text{Cl}$  coincidence peak it is very small.

By rapid evaporation (30 min) of a 4-l. sample of rain water to a small volume it was possible to make a direct measurement of the  $^{36}\text{Cl}$ , and, following its decay, of the  $^{38}\text{Cl}$  in the presence of the relatively large amounts of the natural and artificial radionuclides which are normally present. However, a more satisfactory method was to perform a carrier precipitation of the  $^{36}\text{Cl}$  and  $^{38}\text{Cl}$  as  $\text{AgCl}$  from 0.1 N nitric acid at 50°–60° C in the presence of lead and bismuth carriers. The precipitate is filtered through a membrane filter, washed with 100 ml. hot water then dissolved with 100 ml. 5 N ammonium hydroxide. The ammoniacal solution is acidified by addition of 100 ml. 8 N nitric acid and the chlorides reprecipitated by adding an excess of silver nitrate. The precipitate is filtered through a second membrane filter which is counted directly for a simultaneous  $^{36}\text{Cl}$  and  $^{38}\text{Cl}$  measurement. The residues are evaporated, mixed with the first filter, and placed on a standard counting dish for direct measurement of  $^{35}\text{S}$ , and certain other radionuclides of interest in the sample. The observed concentrations of  $^{35}\text{S}$ ,  $^{36}\text{Cl}$  and of  $^{38}\text{Cl}$  for six rain samples are tabulated in Table 1. The samples were collected by placing a 100–200-ft.<sup>2</sup> plastic sheet on the ground during the light summer showers. The first sample contained the most activity and the measurements, as indicated, are more precise than on the other five samples; however, the latter measurements do give the approximate concentrations and indicate the variations which exist, both in concentration and radionuclide ratios. The rain collection periods ranged from 5 to 50 min, and the concentrations shown were calculated to be those present at the time the rain struck the ground by assuming that the deposition rate of the radionuclides was constant during the sampling period. It is expected that the collection of samples 10 times larger will permit sufficiently precise measurements of these radionuclides and of  $^{23}\text{Na}$  and  $^{24}\text{Na}$  (which can also be measured on this size of sample<sup>10</sup>) to allow cloud formation rates and subsequent wash-out rates by rain to be investigated.

This work was carried out under contract AT (45-1)-1350 for the U.S. Atomic Energy Commission.

## GEOLOGY

### Changes of Sea-level in Southern Australia

RECENT geomorphic investigations in relation to the history of sedimentation and to soil development in the Adelaide, Yorke Peninsula, and Gippsland areas of southern Australia have shown that the varied landforms of these areas are related to a sequence of stranded shorelines which extend from modern sea-level up to a height of several hundred feet. These shorelines are marked by former coastal features, including submarine platforms backed by abandoned sea cliffs, often with beach deposits at their base, coastal foredunes and bars, and notches of marine erosion. Their elevations above mean sea-level and other data relating to them are listed in Table 1.

The successive alluvial terraces of the river systems in the areas investigated are each graded to particular shorelines of the indicated sequence. On Yorke Peninsula, however, drainage was never integrated and alluvial terraces are generally absent. Here valleys are short and the watercourses, now dry, terminate at the coastlines to which they were originally graded. Each successive stillstand in this district brought about anew the development of a few shallow valleys at the new coast, and little or no down-cutting of existing valleys attended each withdrawal of the sea.

Exposures of the alluvial sediments allow a distinction to be made between river terraces due to lateral planation, considered to reflect stillstand of the sea, and terraces due to aggradation, which indicate a relative rise of sea-level. By this means shorelines that record stages of a general recession can be distinguished from shorelines that represent transgressive maxima. In Gippsland, where coastal gradients are very gentle, transgressive shorelines are also recognized by the development of massive foredunes. These impound minor drainage lines and from place to place alternate with abandoned low cliffs.

Some intervals between successive high sea-level stands were characterized by the introduction of aeolian materials, including sief dunes, which mantled the contemporary landscape. These wind-deposited sediments continue at the modern coast to levels now below sea-level, demonstrating a clear correspondence of aeolian sedimentation with former stages of low sea-level, and confirming, for the intervals in which they occur, withdrawals of the sea implied by investigations of the riverine terraces.

The Adelaide and Yorke Peninsula areas lie on opposing sides of the tectonic graben of St. Vincent Gulf. Three major faults pass through the Adelaide area. The last

The letter *R* indicates a regression extending considerably below the level reached by the subsequent transgressive high sea-level. The 600-ft. shoreline of the Adelaide area marks the limit of a marine transgression. The elevations for coastlines above 26 ft. (60 ft. on Yorke Peninsula) are derived from photo-grammetrically contoured maps (contour interval no greater than 25 ft.). Lower coastlines have been surveyed with a dumpy level. The evidence for marine activity at all levels is very well preserved, and the elevations given for the shorelines have an error in the main no greater than  $\pm 2-3$  per cent.

movements on two of these are shown on the field evidence to ante-date the rise of sea-level which culminated in the development of the 600-ft. coastline. Some movements persisted on the third fault after the development of this, and of the later 370-ft. shoreline, but these movements were presumably small, for they failed measurably to dislocate former submarine platforms related to these levels. It is therefore concluded that the shorelines in this area essentially post-date the differential tectonic movements. A shallow graben which passes through the Yorke Peninsula area was invaded by the sea when it occupied the 480-, 420- and 360-ft. levels. These shorelines are nowhere dislocated or deformed. The Gippsland area lies in a separate tectonic province but no evidence has been found of movements within the period of shoreline development.

The repeated changes in level of the sea described here and their accordance from district to district deny hypotheses of land movement relative to a stable sea, and are best explained by supposing that the land has been stable and the sea has moved. This view receives strong support when the levels for southern Australia are compared with the sequence of former sea-levels recorded for the northern hemisphere (Table 1)<sup>1</sup>. This correlation suggests that marine transgressions in southern Australia are to be correlated with interglacials of the northern hemisphere. The marine regressions that have been identified correlate mostly with the known glacio-eustatic depressions of ocean-level. The period of deep erosion, to levels below modern sea-level, which intervened between the development of the 600-ft. and 370-ft. shorelines and which is well attested in the Adelaide area appears to be too great in amplitude to be wholly glacio-eustatic in origin.

Detailed reports on the Adelaide area, which was surveyed by W. T. Ward, and the Yorke Peninsula area, surveyed by R. W. Jessup, are to be published shortly. Work by W. T. Ward is still in progress in the Gippsland area.

### Iron-deficient Low-temperature Pyrrhotite

IN a recent communication<sup>1</sup>, Sawkins, Dunham and Hirst discussed the occurrence of pyrrhotite in low-temperature veins in the northern Pennine orefield. They found that, on experimental inversion and application of the hexagonal pyrrhotite-pyrite solvus curve<sup>2</sup>, monoclinic pyrrhotite in these deposits yields temperatures of deposition markedly in excess of those indicated by fluid inclusion studies. Grønvold and Haraldsen<sup>3</sup>, however, have demonstrated that at temperatures below c. 300° C the stable phases in the iron-rich part of the FeS-S system include troilite, intermediate hexagonal pyrrhotite (Fe<sub>0.936-0.900</sub>S), and monoclinic pyrrhotite (Fe<sub>0.87-0.875</sub>S). These three phases have very restricted ranges of composition, although the compositions of the iron-deficient synthetic phases differ somewhat from those observed in nature<sup>4</sup>. In the light of these relations it seems unreasonable to expect that primary monoclinic pyrrhotite of low-temperature origin co-existing with pyrite will show an iron-deficiency related to temperature of formation by the hexagonal pyrrhotite-pyrite solvus (which probably terminates at some temperature between 250° and 300° C). In the absence of very iron-deficient hexagonal pyrrhotite, the occurrence of troilite and intermediate pyrrhotite, with or without associated monoclinic pyrrhotite, in pyrite-bearing ores may be accepted as evidence that either the initial crystallization or the re-equilibration of the assemblage occurred at temperatures below c. 250° C. I have recently described<sup>5,6</sup> the pyrrhotite assemblages in the Ylöjärvi copper-tungsten deposit, Finland, and have suggested that cooling of hexagonal pyrrhotite from 500° to 565° C to below 300° C resulted in the inversion of much of the pyrrhotite to the monoclinic+hexagonal and monoclinic forms<sup>7</sup>, the formation of hexagonal pyrrhotites having compositions in the range Fe<sub>0.887-0.901</sub>S, and the development of troilite and intermediate hexagonal pyrrhotite (Fe<sub>0.912</sub>S). The last-mentioned two phases form characteristic lamellar intergrowths showing transitions to granular aggregates and monomineralic patches and veinlets. The formation of mackinawite<sup>8</sup> (tetragonal FeS), largely by replacement of magnetite and iron- and copper-sulphides, apparently postdated the crystallization of troilite. In this deposit, the monoclinic and monoclinic+hexagonal pyrrhotites have compositions in the narrow range, Fe<sub>0.869-0.873</sub>S. If inversion from the hexagonal form

was iso-chemical, these compositions would indicate temperatures of formation of 510°–515° C. Because natural monoclinic pyrrhotite shows little departure from the composition,  $\text{Fe}_{0.875}\text{S}$ , however, the close coincidence of the crystallization temperatures deduced from the compositions of the co-existing hexagonal and monoclinic pyrrhotites may be fortuitous<sup>9</sup>. In other sulphide deposits, low-temperature re-equilibration of hexagonal pyrrhotite has resulted in the formation of monoclinic and monoclinic+hexagonal-pyrrhotite, and hexagonal pyrrhotite having a composition in the approximate range  $\text{Fe}_{0.896-0.899}\text{S}$ . Intermediate pyrrhotite ( $\text{Fe}_{0.912}\text{S}$ ) and, especially, troilite may be subordinate or absent in such assemblages (unpublished work).

Table 1. X-RAY DATA FOR PYRRHOTITES FROM THE GREAT SULPHUR VEIN

Locality <sup>10</sup>	Assemblage	Monoclinic pyrrhotite		Intermediate hexagonal pyrrhotite	Troilite
		$d(202)$ (Å)	$d(202)$ (Å)	$d(102)$ (Å)	$d(102)$ (Å)
Aglionby Beck	Quartz, pyrrhotite, pyrite	2-0641	2-0525		
Cross Gill	Quartz, pyrrhotite, pyrite, sphalerite	2-0636	2-0530	2-0707	2-0932
St. John's Mine	Quartz, pyrrhotite, pyrite	2-0635	2-0514	2-0700	2-0936
St. John's Mine	Quartz, pyrrhotite, sphalerite, chalcopyrite	2-0621	2-0522	2-0703	
St. John's Mine	Quartz, pyrrhotite, pyrite	2-0630	2-0538	2-0703	

It should also be emphasized that pyrrhotite occurring, with or without associated pyrite, in low- to high-grade regionally metamorphosed rocks and in unmetamorphosed sediments is generally monoclinic and very iron-deficient. This feature prevents the estimation of the maximum temperatures of metamorphism on the basis of pyrrhotite compositions (unpublished work).

Examination of several pyrrhotite-bearing specimens from the Great Sulphur Vein<sup>10</sup> has shown that, as found by Sawkins *et al.*<sup>1</sup>, monoclinic pyrrhotite predominates over hexagonal, which is represented only by troilite and intermediate pyrrhotite (Table 1). The hexagonal phases have compositions identical to those observed in the Ylöjärvi deposit and at other localities. The ease with which they could be magnetically separated from each other suggests that the troilite and intermediate pyrrhotite occur as granular, rather than fine lamellar, intergrowths.
